IS BIOLOGICAL MATURATION A KEY PREDICTOR OF YOUTH SOCCER PLAYER'S MANAGEMENT OF TEAM PLAY?

RIBEIRO, J.1, BARREIRA, D.1, BAGATIN, R.1, FERNANDES, T.1, ABARGHOUEINEJAD, M.1, PADILHA, B.1, GUIMARÃES, E.1, FERNANDES, R.1, BAXTER-JONES, A.D.G.2, MAIA, J.1

1CIFI2D, FACULTY OF SPORTS, UNIVERSITY OF PORTO;2COLLEGE OF KINESIOLOGY, UNIVERSITY OF SASKATCHEWAN

INTRODUCTION: Typically, the transition from childhood to adolescence is characterized by inter-individual differences in the timing and tempo of changes in body size, shape and composition, all of which effect the physical performance of individuals banded in chronological age groupings. When competing in team sports, were size is related to performance, it is reasonable to expect that those advanced in their maturation outperform their less mature peers. In soccer, this is highlighted by having higher levels of centrality i.e. players playing a key role in managing and/or organizing attacking patterns of team play, in passing networks. Therefore, this study aimed to verify if players with advanced maturity status were central players in teams.
METHODS: The sample comprised 153 soccer players (average age 13.00 ±,83 years) recruited from participants of the In search of excellence in sport–a mixed longitudinal study in young athletes (INEX) study. Biological maturation was estimated using an anthropometric prediction of years from peak height velocity (maturity offset). Players were divided into three maturing groups: late maturers (n=19), average (n=109), and early (n=25) (Wickel & Eisenmann, 2007). Data on game performance was obtained from participation in GK+4vs.4+GK matches (n=16) and analyzed using SocNetV v2.2.1 to assess the degree of centrality (defined as the number of passes received (PR) and performed (PP)), betweenness centrality (BC-quantifies the number of times a player connects other pairs of players), and closeness centrality (CC–how close a player is to his teammates) of each player. Group means were tested by ANOVA; alpha=5%.
RESULTS: Descriptive statistics for each maturity group were: late PR(15.37±7.39), PP(16.26±5.78), BC(0.51±0.88), CC(0.45±0.15); average PR(13.90±7.42), PP(13.59±5.74), BC(0.35±0.66), CC(0.39±0.16); early PR(13.92±9.08), PP(15.40±6.80), BC(0.52±0.78), CC(0.40±0.16). There was a tendency for late maturers to present the highest values of centrality as verified in values of PR, PP, and CC, although results were not statistically significant (p>0.05).
CONCLUSION: Apparently, differences in biological maturation statuses are not associate with centrality. However, our results revealed a non-significant trend for late maturers to be the central players. Possibly, this group might have displayed other key resources (e.g., higher technical skills) comparatively with the other two groups that can be significant determinants for predicting players' centrality in teams. Therefore, coaches should be aware of such implications when preparing their training sessions by adopting strategies that can promote equal learning opportunities for all players, regardless of their maturity statuses. Players need to be continuously involved in competitive settings instead of being excluded due to inter-individual differences motivated by distinct maturity differences.

ASTHMA AND ALLERGIES WITH REFERENCE TO PULMONARY FUNCTION, RESPIRATORY SYMPTOMS AND PRESCRIBED MEDICAL TREATMENT IN COMPETITIVE SWIMMERS

PÄIVINEN, M., KESKINEN, K., PUTUS, T., KUJALA, U., KALLIOKOSKI, P., TIKKANEN, H.

UNIVERSITY OF TURKU AND UNIVERSITY OF HELSINKI

INTRODUCTION: Asthma and respiratory symptoms are more common in competitive swimmers, than in general population. Ensuring to maintain good pulmonary health and optimal performance level in highly trained competitive swimmers is crucial. The aim was to investigate asthma and allergy medical background, respiratory symptoms, pulmonary function, and prescribed medical treatment in swimmers.
METHODS: National champion ships swimmers, total of 130 (57 females and 72 males), were studied. Swimmers participated pulmonary function testing by flow-volume spirometry and filled questionnaire concerning medical history, asthma, allergy, prescribed medication and
respiratory symptoms in connection to swimming.
RESULTS: Spirometry testing showed that mean forced vital capacity (FVC) was 112% and forced expiratory volume in one second (FEV1) 108% of predicted even though 12% of studied swimmers had airway obstruction finding. Forty percent, 52 out of 130 swimmers reported physician prescribed medication for asthma, allergy or both. However, 5 swimmers with both asthma and allergy did not report any medication.
CONCLUSION: Pulmonary function in competitive swimmers was higher than predicted, but the prevalence of airway obstruction findings was high and despite asthma diagnosis and physician prescribed medication for asthma. These results show that there may exist gap between the asthma and allergy treatment and the optimal state of pulmonary function in highly trained National champion ships level competitive swimmers.

THE RELATIVE AGE EFFECT IN POLAND`S YOUTH VOLLEYBALL

RUBAJCZYK, K., POPOWCZAK, M., ROKITA, A.

UNIVERSITY SCHOOL OF PHYSCIAL EDUCATION IN WROCLAW

INTRODUCTION: In volleyball, the height of a player's body is a key selection factor. The calendar age difference between competing players may be up to 12 months, and players born at the beginning of the calendar year are often favoured because of their natural physical advantage. The requirements for volleyball players are constantly changing during the game (Shepard at all., 2009). Technical skills are one game-related performance factor which contributes to the success of sports teams (Peña et all., 2016). Having the appropriate anthropometric characteristics is a requirement for professional volleyball players (Pion at all., 2015). The Olympic Hopes Tournament (OHT) was organized in 2004 for Polish volleyball, and this tournament exemplifies the difficulty in the identification of talent in youth

sports using a traditional approach. We hypothesized that the players selected for the National Volleyball Development Programme (NVDP) from OHT would present a taller body height and a higher level of motor skills than the unselected players.
METHODS: Data on the date of birth, anthropometric characteristics were obtained for girls (n=2152; aged 13-14) and boys (n=2213 aged 14-15). Agility was measured using a modified zig-zag test. The explosive power was assessed by medicine ball throw. Date of birth data were listed in four quarters of the calendar year. One-way analysis of variance (ANOVA) was used to determine differences in anthropometric characteristics and motor test results. Performance characteristics were analysed using a stepwise discriminant function analysis to determine which combination of the measured characteristics optimally explained the decision for qualify player to NDVP. In this analysis, group (selected to NDVP vs. not selected players) was the dependent variable and the performance characteristics and age were the independent variables.
RESULTS: The RAE was most visible in the NVDP boys group ($\chi^2 = 52.81$, $p < 0.0001$, $V = 0.29$, Q4 = 6.03%). The NVDP players were heavier and taller than the OHT participants who were not selected for central training ($p < 0.0001$). The analyzed groups did not differ significantly in the mean time obtained in the volleyball agility test. Our model demonstrated that a combination of five (female) and four (male) characteristics optimally discriminated between the selected to NDVP and non-selected players.
CONCLUSION: In support of our hypothesis, players selected for the National Volleyball Development Programme (NVDP) from OHT were taller body height and a higher level of motor skills than the unselected players. Additionally, the RAE was the most visible only in the group of boys selected for the NVDP. The practical application of this study results by volleyball coaches and federations should be incorporated during the reconstruction of the talent identification models, especially during training camps such as OHT.

SLEEP CHARACTERISTICS OF ELITE ATHLETES: COMPARISON BETWEEN SUBJECTIVE SLEEP QUESTIONNAIRE REPORTS AND OBJECTIVE MEASURES USING MONITORING DEVICE

KISLEV-COHEN, R.1, SHARGAL, E.1, BAHARAV, A.2

1: WINGATE INSTITUTE, 2: HYPNOCORE LTD

INTRODUCTION: Sleep is a basic requirement of human health and known to be an important factor in the recovery process of athlete from training. Furthermore, a growing body of research have demonstrated the positive relationship between sleep and optimal performance. However, studies in recent years demonstrated that athletes often have low sleep quality and quantity. The aim of the present investigation was two folds, first to quantify and characterize sleep in elite athletes from various national teams in Israel, and secondly compare the subjective reports vs. objective sleep characteristic measures.
METHODS: 1485 individual nights of sleep of a cohort of eleven elite athletes (7 females and 4 males, mean age: 24.18+3.74, mean no. of nights of recordings per athlete = 135+66) were analyzed. The athletes were elite athletes from various sports (Fencing, Judo, Windsurfing, athletics and swimming). The athletes monitored their sleep using a mobile app (SleepRate by HypnoCore) and a monitoring plate placed underneath their mattress (EarlySense, Israel). Sleep evaluation was performed using a validated algorithm which is based on heart rate variability (HRV) and a short digital subjective sleep questionnaire was filled by each athlete each night and morning.
RESULTS: Mean measured total sleep time (TST) was 437.18+42.73 min, mean sleep efficiency (SE) was 86.32+2.74%, mean sleep onset (SO) was 31.27+6.43 min, mean percentage (%) deep sleep stage (DS) and % REM stage (REM) were 23.9% and 16.54% respectively. A significant differences were found between the subjective reports and the objective measures, both TST and SE were reported to be higher than actually measured (466.57+45.53 vs. 437.18+42.73 min P=0.001, 91.81+3.06 vs. 86.32+2.74%, P=0.04 respectively) and SO was reported to be shorter than actually measured (31.27 +6.43 vs. 25.59+11.44min, P=0.0001).
CONCLUSION: The results indicated that the athletes monitored had rather adequate TST compared to other reports on elite athletes in the literature, but still should try to improve their total sleep duration and sleep efficiency. Since, significant differences were found between the subjective sleep reporting and the objective measures, the use of questionnaires to monitor sleep duration and quality in elite athletes should be questioned and taken with precaution.

MOTION ANALYSIS OF ELITE SOCCER GOALKEEPERS

LIPINSKA, P., ASCHENBRENNER, P., SZWARC, A., CHAMERA, M., JASZCZUR-NOWICKI, J., PADULO, J., CHAMARI, K.

KAZIMIERZ WIELKI UNIVERSITY

INTRODUCTION: Needs of modern team game require accurate analyses in order to rationally manage the players' training process with the aim of ultimately improve performance. Establishing activity profile of the player is one of these elements. In particular, the distance covered in the game is considered to be the players activity, as well as velocity and acceleration which indirectly characterize players game involvement. The goalkeeper plays a special role in the soccer game. He is required not only to defend the goal, but also to actively cooperate with other players both during defending and attacking. Therefore the aim of this study was to determine the time motion characteristics of elite goalkeepers during official games: distance covered in situation of game won, drawn and lost.
METHODS: Seventeen goalkeepers from Polish National League teams were monitored in15 matches. Their activities were recorded during the entire match by two cameras (NEX-VG30EH Interchangeable lens Full HD camcorder, Sony Corp., Japan) with a sampling rate of 210 Hz. Goalkeeper's Activity Index (GAI) was applied to assess their engagement into the game. The distance covered by each goalkeeper and the velocity of the movement was calculated using AS-4 software. Movement analyses were carried out distinguishing four categories of motion (standing, 0<0.4 km/h; walking/jogging, 0.4≤12 km/h; low-/moderate-/high-speed running, >12<23 km/h; sprinting, ≥23 km/h).
RESULTS: Elite goalkeepers covered 72.7%, 25.8%, and 2.5% of the distances during the game by walking/jogging, running, and sprinting, respectively. Goalkeeper's covered slightly higher distances in lost matches than in matches ending in a win or drawn (4800 ± 906m, 4696 ± 1033m, and 4660 ± 754m, respectively). There were no significant differences between distances covered in the first and second halves. Distance covered by goalkeepers during a match was about half of distance covered by players from the field, but the profile of their motor activity was similar to the players playing on other positions. The area of most frequent activity was the mid sector of penalty area between goal and penalty area lines. ANOVA showed that in drawn matches goalkeeper's activity significantly differed in mean values of GAI in comparison to won and lost game (p=0.034, p=0.039, respectively). Goalkeeper' involvement in the game was higher in the second halves of matches, and in the last stages of each part of the game. It was noted that goalkeepers tended to intervene more often in games where their team was winning, rather than in these ones with losing result.
CONCLUSION: Determination of specific requirements for goalkeepers within the motor activity and engagement in the game depending on the time and game result, can enable better preparation (motor, technical and tactical) of goalkeeper for the competitive game.

THE ROLE OF BASKETBALL CLUBS COMPETITIVE LEVEL ON TECHNICAL SKILLS DEVELOPMENT DURING YOUTH: THE INEX PROJECT.

GUIMARÃES, E.1, RIBEIRO, J.1, BAGATIN, R.1, FERNANDES, T.1, ABARGHOUEINEJAD, M.1, TAVARES, F.1, BAXTER-JONES, A.D.G.2, JANEIRA, M.A.1, MAIA, J.1

1CIFI2D, FACULTY OF SPORTS, UNIVERSITY OF PORTO; 2COLLEGE OF KINESIOLOGY, UNIVERSITY OF SASKATCHEWAN

INTRODUCTION: High performance basketball requires, even during adolescence, exceptional physical and physiological attributes (1). Top-level technical skills (TS) are very important in identifying excellence in youth players (2). It is well-known that age, sex and competitive level differences are amplified by inter-individual differences related to biological maturation (biological age) and training experience (3). Thus, aligning individuals by biological age rather than chronological age, this study aims to investigate the effects of clubs´ competitive level on young basketball players´ TS changes.
METHODS: The present study is part of a project entitled In search of excellence in sport - a mixed-longitudinal study in young athletes (INEX). Using a mixed-longitudinal design, 281 young basketball players, aged 10 to 16 years, were followed consecutively for 18 months, assessed every six-month. Players were divided into elite (n=101) and non-elite (n=180) groups based on their clubs´ competitive level. Biological maturation, training experience and fat-free mass were assessed. TS were assessed using the AAHPERD basketball-specific test battery, as well as the Slalom Sprint and the Slalom Dribble tests. All test results were standardized and summed to obtain an overall z-score measure of TS performance (TTSz). A multilevel model (repeated observations nested within players) was developed using SuperMix 2.0; alpha=5%.
RESULTS: TTSz scores increased linearly (b=3.47±0.25, p<0.001), but no significant effects were observed for players´ competitive level (b=0.24±0.37, p=0.516), nor for interactions with biological age (b=0.21±0.22, p=0.336). On average, more experienced players were more skillful in TTSz (b=0.36±0.09, p<0.001). With increasing fat-free mass players´ TTSz performance declined (b=–0.21±0.35, p<0.001). Furthermore, significant inter-individual differences were observed at baseline (variance=5.20±0.78, p<0.001) and in TTSz changes over time (variance=0.61±0.26, p<0.001). Baseline TTSz performance did not condition players´ trends across time (covariance=–0.12±0.25, p=0.605).
CONCLUSION: Our study indicated no overall technical performance differences between elite and non-elite young players. This suggests that player's skill development is apparently similar in their response to training and competition, i.e., independent of clubs´ competitive level. We anticipate that in such age-categories coaches invest quite enough practice time in the acquisition and development of these skills and all are similarly successful. Nevertheless, it is important to be aware of the critical role of training experience, in order to increase success opportunities for all players irrespective of their level of expertise.

EFFECTS OF DUET FREE ROUTINE TRAINING ON MOVEMENT QUALITY AND INTENSITY IN ARTISTIC SWIMMERS DURING A 12-WEEK COMPETITION PERIOD

KOMORI, Y., OKAMOTO, Y., SHIMURA, Y., INOUE, M., HOSHINO, S.

KYOTO KOKA WOMENS UNIVERSITY

INTRODUCTION: Artistic swimming is a competitive sport, judged on the basis of the synchrony between music and the movements of each swimmer. An artistic swimming competition includes figure and routine sessions. The duet free routine does not require predetermined elements to perform; a much greater emphasis is placed on the creativity of the choreography and movement. Judgement of the duet free routine was evaluated on the basis of execution (the level of excellence in performing highly specialised skills), artistic impression, and difficulty (the quality of all movements). Therefore, physiological and technical factors are important for artistic swimmers in performing the duet free routine.
The purpose of this study was to examine the effect of 12 -weeks of duet free routine training on movement quality and movement intensity in elite artistic swimmers.
METHODS: Two female artistic swimmers (n=2, aged, 18 years) who represented the Kyoto Prefecture at the National Athletic Meet in Japan participated in this study. The performance indicators of the duet free routine were as follows: (1) heart rate (HR) during performance, (2) movement intensity during technical movement (%HRR), (3) rate of perceived exertion (RPE) immediately after performance, (4) subjective evaluation of technical movements (5-point scale), and (5) judgement of the duet free routine by the referees. These indicators were measured 3 times (test 1, June; test 2, July; test 3, August) during the 12-week 2017 competition period.
RESULTS: HR values during the duet free routines were 150.3 ± 15.7 bpm, 150.6 ± 13.3 bpm, and 158.3 ± 19.3 bpm in test 1, test 2, and test 3, respectively ($p < 0.01$). Movement intensity values were 73.3 ± 1.3%, 69.5 ± 0.7%, and 75.8 ± 0.7% in test 1, test 2, and test 3, respectively ($p < 0.001$). HR and movement intensity values in test 3 were higher than in test 1 and test 2. Additionally, the subjective evaluation scores for the technical movement and judgement scores by the referees were higher in test 3 than in test 1.
CONCLUSION: These findings indicate that training during the competition -period results in improved evaluation scores for technical movements and performance as judged by the referees.
In conclusion, the results of this study suggest the importance of enhancing the quality of movements, even under high movement intensity, on the performance of artistic swimmers during the competition period.

ARE THERE REGIONAL DIFFERENCES IN RELATIVE TERRAIN PERFORMANCE IN THE CROSS-COUNTRY SKI SPRINT PROLOGUE?

BUCHER, E., BRUHIN, B., TRÖSCH, S., STEINER, T., WEHRLIN, J.

SWISS FEDERAL INSTITUTE OF SPORT, MAGGLINGEN, SWITZERLAND

INTRODUCTION: The cross-country ski sprint prologue involves a 2 – 4 minute time-trial on varying terrain with the top 30 skiers advancing to the subsequent finals. Qualification success not only depends on physiological and technical capacity, but also on optimal pacing strategy and appropriate relative efforts in flat, uphill and downhill terrain (1). Traditionally, skiing Nations have formed performance trends and skiing techniques over time (2) and anecdotal coaching opinions suggested the existence of terrain-dependent performance differences between nationalities and regions.
METHODS: During the U23 Cross-Country Ski World Championships 2018 freestyle sprint prologue in Ulrichen, Switzerland, skiing performance in flat, uphill and downhill terrain was analyzed using time-synchronized video recordings and official race timing data. Athletes skiing within 10% difference of the winning time-trial performance were included (female skiers = 43; male skiers = 64) and categorized into the regional groups of European Alpine Region (ALP), Scandinavia (SCA), Asia (ASI), and America (AME). Relative performance indices for flat, uphill and downhill terrain were calculated (velocity in specific terrain divided by average skiing velocity over the entire race course) for each skier. Regional differences in terrain performance indices were analyzed using repeated measures ANOVA for female and male skiers pooled.
RESULTS: Terrain performance indices for the four regions ALP, SCA, ASI, and AME were 1.22 ± 0.03, 1.23 ± 0.02, 1.24 ± 0.03, and 1.23 ± 0.04 for flat terrain; 0.60 ± 0.03, 0.61 ± 0.03, 0.60 ± 0.03, 0.60 ± 0.03 for uphill terrain; and 1.78 ± 0.05, 1.76 ± 0.04, 1.77 ± 0.06, 1.79 ± 0.05 for downhill terrain, respectively. No statistically significant effect was observed regarding regional background of the skiers ($p = 0.998$).
CONCLUSION: Relative skiing efforts in flat, uphill and downhill terrain during an international cross-country ski sprint time-trial did not differ between elite skiers of different regional origin. The current findings suggest, that overall pacing strategies applied during the sprint course are similar among skiers of different backgrounds. Furthermore, it can be speculated that the terrain-specific performance characteristics in these elite athletes appear to be developed similarly and independent of potential differences in regional skiing and coaching traditions.

FASTBREAK CHARACTERISTICS IN U18 WOMEN'S BASKETBALL CHAMPIONSHIP 2018

CHIANG, H.Y., LAN, Y.C., LIU, Y.T.

NATIONAL EXPERIMENTAL HIGH SCHOOL AT HSINCHU SCIENCE PARK

INTRODUCTION: Fast break is one of the important strategies in basketball offense and is considered favorable to be applied for young players (Monteiro et al., 2013). Research on the fast break performances has mainly been focused on professional basketball.The purpose of this study was to examine the characteristic of fast breaks in the Asian U18 Women's Championship 2018, specifically the relationship between the way the fastbreakswere initiated and the efficacy of the fast breaks.
METHODS: There were 578 fast breaks analyzedfrom 25 games of the Asian U18 Women's Basketball Championship 2018. Fast breaks were defined as those ball possessions whose duration were under 5 seconds. In addition to the duration of the ball possession, types of ball recovery and the results of the ball possessions were also recorded. The Cohen's Kappa for the intra- and inter-observer reliability rangedfrom 0.85 to 0.97 for two observers. The Chi-squared test of independence wasused to examine the association between the duration and type of ball recovery for the number of fast breaks and the successful fast breaks.
RESULTS: Thirty six percent of the fast breaks were initiated from the passing interception, followed by 31% of the defensive rebound. The average success rate of the fast breaks was 47%. There were significant associations between the type of ball recovery and the duration of ball possession for both the number of fast breaks and the number of the successful fast breaks ($ps<.001$). Specifically, the positive high associations were found between the passing interception and under 2 seconds duration, as well as between the defensive rebound and 4-5 seconds duration.
CONCLUSION: The success rate observed from the Asian U18 women's basketball championship was not as high as those reported in young man (60%, Monteiro et al., 2013) or adult women (66%, Refoyo et al., 2009) indicating an inferior performance level for these players. The high percentage of the passing interception in initiating the fast breaks may also indicate the unstable passing skills for the players.The high associations between the types of the ball recovery and the duration in the successful fast breaks provide tactical information inplanning training programs and implementing game tactics for coaches.

STRUCTURE OF FAST BREAKS IN PROFESSIONAL WOMEN'S BASKETBALL

LAN, Y.C.1, LIU, Y.T.2

1: NATIONAL YANG-MING UNIVERSITY, 2: NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Fast break is the most effective offense tactic in basketball (1). Research on fast break characteristics has mainly focused on the contribution of individual element to fast break such as type of ball recovery, duration of fast break, and number of participating players. The purpose of the study was to examine the relation among the type of ball recovery, duration of ball possession, and the number of participating attackers and defenders of fast breaks in professional women's basketball.
METHODS: There were 1991 ball possessions, including 699 successful ones, analyzed from 51 games of the 2017 WNBA regular season and playoff. The type of ball recovery, number of attackers and defenders, as well as the duration of ball possession were recorded for all the ball possessions that lasted 8 seconds or less. Data were recorded by 2 independent observers and the Cohen's Kappa were 0.92 and 0.88 for the intra- and inter-observer reliability, respectively. Chi-squared tests of independence were performed on the number of ball possession and successful ball possession to examine the association among the type of ball recovery, duration of ball possession, and the relative number of attacker-defender.
RESULTS: There were significant associations for the number of possessions and successful possessions between the duration and relative number of players, between the duration and type of ball possessions, as well as between the relative number of players and type of

ball possessions, ps<.001. The possession duration of 1-4 s was associated with interception and steal, and both were associated with attacker advantage. The 5-6 s duration was associated with defensive rebound, and both were associated with defender advantage. The 7-8 s duration was associated with ball recovery type of field goal, and both were associated equal number of attackers and defenders.
CONCLUSION: Fast breaks in Basketball has been associated with attacker advantage and short durations. The findings of the study confirmed that attacker advantage was mainly available when the offense completed within 4 s and the majority of these ball possessions were initiated from the actions of intercepting passes and steals from the opponents. Possession durations of 5-6 s presented the transition phase from fast break to set offense where most of these possessions were from defensive rebound and with a disadvantage of the number of attackers. At ball possession duration of 7-8 s, the offensive systems started to transition to the set offense where equal number of attackers and defender were involved in the play and the ball recovered from the field goal of the opponents was the main source of possession initiations. The study presents a basic structure of fast break system. Future study may include more performance variables such as type of shots and location of shots made to provide a comprehensive understanding of the fast break system.

KNOWING THE NEUROMUSCULAR SYSTEM IN SOCCER PLAYERS ALLOWS PREVENTING INJURIES

FERNÁNDEZ-BAEZA, D., GONZÁLEZ-GONZÁLEZ, J., SALINERO, J.J., NAVARRO CABELLO, E., MAN, H., AGUIRRE, J., GONZÁLEZ-MILLÁN, C.

UNIVERSITY FRANCISCO DE VITORIA, SPAIN

INTRODUCTION: The strenght and the time of apliccation are decisive aspects of the neuromuscular soccer player´s system for their competitive performance. Knowing the neuromuscular situation we cant prevent injuries. Neuromuscular system has recently begun to be analysed by means of tensiomyography (TMG), a non-invasive technique that can measure the properties of individual superficial muscles by recording the isometric muscle contraction induced externally by electrostimulation (1,2). This technique has been also useful as an evaluation tool for muscular impairment in a number of conditions (3).The objective of this study is to determine the contractile properties of the flexor and extensor muscles of the knee in soccer players in season.
METHODS: 17 soccer players were evaluated by means of TMG (TMG Measurement System, TMG-BMC Ltd., Slovenia). They were measured maximum radial muscle belly displacement (DM), contraction time (TC) and lateral symmetry of the muscles vastus medialis (VM), vastus lateralis (VL), rectus femoris (RF), biceps femoris (BF) and Semitendinosus (ST). The DM corresponds to the radial movement of the muscle belly expressed in millimeters and is related to muscle belly stiffness. The TC is obtained by determining the time lapse from 10% to 90% of DM. A paired-samples t test ($p < .05$) was used to compare the dominant and non-dominant lower limb, and to compare forward and midfield players.
RESULTS: The muscles with a shorter TC were the VM and VL of both legs (VL right: 19,57±2,8 ms; VL left: 20,2±1,79 ms; VM right: 21,95±3,15 ms; VM left: 22,80±3,14 ms). The muscle with less DM and with more stifness was the VL right (3,79±1,30 mm). The highest degree of lateral symmetry corresponded to the VM (87,17±7,32%), and the lowest to the RF (74,11±12,01%). No differences were observed between the dominant and non-dominant leg. Only significant differences were found ($p <0.01$) between midfielders (5.19±2.15 mm) and fordwards (3.97±0.63 mm) in the DM of the BF left leg (more stifness in fordwards). The functional symetry between extensor and flexor chain was lower in the right leg (76±12.05%) respect to the left (78,7±11,11%). Between both vastus the functional symmetry was elevated and similar in both legs. (right 82,11±8,14%, left 83,82±7,09%).
CONCLUSION: TMG was shown to be a useful way of evaluating the neuromuscular characteristics of soccer players to prevent injuries. The DM in the BF muscle in forwards presents values compatible with injuries. The VL muscles are the most explosive muscles. The VL muscle of the right leg has reduced DM values compatible with injury. There are differences in RF between both legs (although not significant). The functional symmetry in the right leg is low, which can lead to injury risk.

ARTIFICIAL INTELLIGENCE CAN PREDICT NON-CONTACT INJURIES IN SOCCER

ROSSI, A., PAPPALARDO, L., CINTIA, P.

UNIVERSITY OF PISA

INTRODUCTION: Injuries have a negative influence either on the mental state of soccer players, on the performance of a team and on the finance resources of a club, due to the considerable costs of rehabilitation (Hägglund et al., 2013). In this paper, we provide an artificial intelligence approach to forecast injuries in soccer using the training workload recorded through GPS devices.
METHODS: For each training session, Global Position System (GPS) tracking data related to 22 soccer players of an Italian club has been collected over 23 weeks. For each player, 55 features describing training workloads were extracted from GPS data and the club's medical staff recorded 21 non-contact injuries during the season. In this study, we investigate a "real-world" scenario where we train and test a machine-learning algorithm for injury prediction as the season goes by. At training week i we first construct the dataset consisting of all the training examples collected up to week i. We then oversampled the injury examples to balance the dataset and reduced the feature space through recursive feature elimination. We use the dataset build at week i to train a Decision Tree Classifier (DT) and try to predict the injuries in week i+1. We compare DT with a baseline B that forecasts injuries using the state-of-the-art Acute and Chronic Workload Ratio (ACWR) as indicated by Gabbet at al. (2010). The goodness of the forecasting is assessed by F1-score, defined as the harmonic mean of precision (i.e., proportion of correct positive injury identifications) and recall (i.e., proportion of injuries correctly identified).
RESULTS: Just 3 features out of 55 are selected by the recursive feature elimination: number of previous injuries (PI), number of decelerations (DEC) computed as the exponential weighted moving average of the previous 6 days, and high metabolic load (HML) computed as the ratio between the mean and the standard deviation of the values of the feature in the last week. DT results in a cumulative F1-score =

0.60 (i.e., precision = 0.50 and recall = 0.80) on the injury class, much better than the baseline (cumulative F1-score = 0.07 +/- 0.1). Finally, we observe that the performance of DT stabilizes after 14 weeks of data collection.
CONCLUSION: The good performance of DT compared to the baseline indicates that the injury forecaster is reliable due to its high precision, strongly reducing false alarms. An initial period of data collection is needed in order to gather the adequate amount of data to train the machine learning model. The length of the data collection period depends on the clubs needs and strategy such as the frequency of training sessions and games and the number of injuries occurred.

WORKPLACE INTERVENTION TO REDUCE THE DOUBLE-CRUSH-PHENOMENON

GRÄF, J., LÜDTKE, K., WOLLESEN, B.

UNIVERSITY OF HAMBURG

INTRODUCTION: Malposture is a major risk factor for developing musculoskeletal disorders such as neck or hand pain, especially in the industrial work space (da Costa & Vieira, 2010). In the context of the double-crush-phenomenon (DCP), manual repetitive tasks and ergonomically not optimal neck postures during precision work with magnifying lenses may increase the risk for developing a Carpal Tunnel Syndrome (CTS). This relation between neck malposture and CTS describes concomitant compressions at two or more peripheral nerve sites which is compressed at its origin due to severe flexion in the cervical spine. This leads to a higher susceptibility and further irritations in the periphery (Cohen, Gaspar, Daniels, Akelman, & Kane, 2016). The aim of this study was to compare the upper body posture, the muscle activity and the perceived exertion when using the magnifying lens system and a novel camera system as an ergonomically optimized workplace tool. The camera system should induce a more upright neck posture with a straight view.
METHODS: In a randomized crossover study design, N = 16 healthy subjects (28 ± 5 years) performed tests in two different settings (magnifying lenses (ml) and the novel camera system (nc)) and two different body postures (sitting and standing). The muscle tension of the m. trapezius pars descendens was measured by surface electromyography (sEMG), the analysis of neck and shoulder positions were measured via 2-D kinemetry and the perceived exertion via Borg Scale served as primary and secondary outcomes.
RESULTS: The use of the novel camera system resulted in a more neutral neck position (ml: 28.5° ± 9.6°, nc: 43.6° ± 7.1°, $F(2,05;30,72) = 36.68$; $p < 0.001$; $\eta p2 = 0.710$), a reduced muscle load (ml: 15.6% ± 12.9%, nc: 9.9% ± 6.2%, $Chi2(3) = 11.475$; $p = 0.009$) and a lower level of overall and neck specific perceived exertion (overall ml: 10 ± 2, nc: 9.5 ± 2, $Chi2(3) = 10.56$; $p = 0.01$; neck ml: 10.5 ± 2.5, nc: 9 ± 2, $Chi2(3) = 10.54$; $p = 0.02$) . In addition, a more neutral wrist position was observed, which minimized the stress in this region and thereby the risk to develop CTS.
CONCLUSION: The novel camera system can reduce the risk of DCP and subsequently of CTS by achieving a more upright neck position during manual repetitive precisions tasks. The effects of the manual repetitive task had a lesser impact than the neck position itself. Generally, this shows the importance of ergonomically designed workplaces to prevent musculoskeletal disorders and to maintain the health of employees, especially in the industrial work setting.

STRENGTH TRAINING AND SHOULDER PAIN IN MALE AND FEMALE WATER POLO PLAYERS

TORRES-UNDA, J., BARRENETXEA-GARCÍA, J., DUÑABEITIA, I., BIDAURRAZAGA, I., ESAIN, I., GIL, S.

UNIVERSITY OF BASQUE COUNTRY

INTRODUCTION: The incidence of shoulder pain in water polo is higher than in most sports (1). Although some factors like throwing frequency or muscle imbalances have been associated with higher prevalence of shoulder soreness in water polo players, contributors to painful condition are poorly understood (2). As has been described in other areas, specific strength training should contribute to improve player biomechanics resulting in a better performance and in a reduction of shoulder pain (3). The aim of this project was to investigate the relation between strength training protocols and shoulder pain in both male and female players.
METHODS: Male (n=24) and female (n=16) water polo players were randomly allocated into a maximum strength training (MS) or power training (P) groups. All of them completed a 12-week training protocol. Before and after the intervention, players´ anthropometry was assessed, shoulder external and internal rotation were measured by isokinetic, and functional test, such as hand dynamometry, throwing velocity and swimming speed were performed. In addition, shoulder pain was assessed by visual analogic scale after each training session.
RESULTS: After the 12-week training protocol, no changes were observed in anthropometry. Shoulder pain increased after the intervention in MS ($p<0.05$) and P ($p<0.001$) training groups. Improvements in the performance of isokinetic and functional tests were not found, except for handgrip test only in male players ($p<0.05$). On the contrary, a decreasing trend in shoulder rotation strength was found in all players. Particularly, female players of P group showed at the end of the protocol lower values of internal rotation strength ($p<0.05$). Furthermore, women performed worst throwing speed test at the end of 12 weeks in comparison with baseline ($p<0.05$). Speed of the swimming test did not significantly change from the beginning to the end of the protocol.
CONCLUSION: Strength training is related to shoulder pain in water polo players, especially P training protocols. In addition to a higher risk of painful condition, specific MS- and P-based training protocols do not seem to influence positively players´ performance. Consequently, further investigations are required to develop new specific training methods focused on shoulder pain prevention in water polo players.

PRELIMINARY STUDY ON THE USE OF EMG-AUDIO FEEDBACK TO INDUCE MUSCLE COACTIVATION: IMPLICATIONS FOR INJURY PREVENTION AND REHABILITATION.

PINTO, T.P., DOS ANJOS, F., GAZZONI, M., VIEIRA, T.

POLITECNICO DI TORINO

INTRODUCTION: Unbalanced activation between hamstring and quadriceps during sport-related activities has been suggested to lead to muscle-skeletal disorders. While general concern recommends focusing on the coactivation of knee flexors/extensors as a potential preventive and rehabilitative mechanism, maximising coactivation during movement has proved a difficult task (1-3). Here we investigate whether audio biofeedback from surface electromyograms (EMGs) could assist subjects in exercising with maximal muscle coactivation.
METHODS: Two male subjects participated in this preliminary study. Each performed ten repetitions of three different exercises: walk lunge with each leg; squat; vertical jump. Trials were applied twice, without and with audio feedback, from bipolar EMGs collected bilaterally from vastus lateralis (VL), vastus medialis (VM), semitendinosus (ST) and biceps femoral (BF). During biofeedback tasks, subjects were instructed to increase the volume of an audio signal proportional to the ratio between hamstring and quadriceps muscles' activity. For walk lunge and squat exercises they were asked to increase the volume during the whole movement (eccentric and concentric phases), while for jump exercise only during the landing phase. Coactivation ratio was calculated by dividing the normalized Root Mean Square (RMS) amplitude of hamstring muscles (averaged between ST and BF) by the normalized RMS of quadriceps muscles (averaged between VL and VM). The effect of EMG-audio biofeedback on muscle coactivation was assessed for each exercise repetition, separately for each leg and phase of movement identified with an electrogoniometer. Mann–Whitney U test was applied to assess EMG-audio biofeedback effect on coactivation ratios for each subject separately.
RESULTS: On average, for walk lunge and squat exercises coactivation ratios were higher with than without EMG-audio biofeedback, with statistical significance ($p<0.05$) for: walk lunge (both legs and phases) and squat (left leg, eccentric phase) for subject 1; walk lunge (right leg, both phases) and squat (right leg, eccentric phase; left leg, concentric phase) for subject 2. For jump exercise there was no difference between conditions, except for the right leg of subject 2, where coactivation ratio was significantly lower with than without EMG-audio biofeedback.
CONCLUSION: Preliminary results indicate the two subjects tested were able to increase coactivation of knee extensors/flexors with EMG-audio biofeedback. If these preliminary results extended to the sample of subjects we are currently testing, it would suggest EMG biofeedback could be a promising technique to improve coactivation during exercises focused on injury prevention and rehabilitation.

LANDING ERROR SCORING SYSTEM CALCULATION METHOD CAN MAKE AN IMPORTANT DIFFERENCE!

HANZLIKOVA, I., HEBERT-LOSIER, K.

UNIVERSITY OF WAIKATO

INTRODUCTION: It is essential that assessment outcomes are reproducible and comparable between studies to improve healthcare management and science inference. The Landing Error Scoring System (LESS) is a valid and reliable tool used to identify athletes presenting high injury-risk biomechanical patterns [1]. Three drop-jumps are typically assessed; however, since the original LESS paper [1] did not explicitly state how to calculate the "final" score for a given individual (i.e., use of mean or best trial score), 5 different final LESS score calculation methods are present in the literature. Our aim was to explore whether calculation methods significantly influence the final LESS score.
METHODS: 328 participants (169 males, 159 females) performed 3 x 30-cm drop-jumps. The original LESS protocol and scoring system were used to extract LESS scores [1], where scores can range from 0 to 17 errors. Subsequently, the final LESS score was calculated for every participant according to 5 methods: mean score, 1st jump score, 3rd jump score, best jump score, and score from the sum of errors present in at least 2 jumps. The influence of calculation method on group mean LESS score and group-level risk categorisation using a LESS threshold of 5 (high risk: LESS ≥ 5 errors) were estimated using Generalized Estimating Equations, with the mean score set as reference method. In terms of individual-level risk categorisation, the agreement in risk categorisation versus the reference method was assessed using odds ratios (OR) and McNemar's tests. Uncertainty in estimates were quantified using 95% confidence intervals [lower, upper].
RESULTS: The estimated score of participants using the mean score was 5.90 [5.64 to 6.19] errors and OR of being at high risk was 1.15 [0.87 to 1.42]. Compared to the mean score reference method, LESS scores using the 1st jump and best jump calculation methods were on average -0.14 [-0.43, 0.12] ($p = 0.014$) and -0.90 [-1.19, -0.64] ($p < 0.001$) lower. Group-level risk categorisation was significantly different from the mean score reference method for the best jump (OR: -0.69 [-0.96, -0.41], $p < 0.001$) and sum of errors present in at least 2 jumps (OR: 0.19 [-0.08, 0.46], $p = 0.033$) methods. At an individual level, differences in risk categorisation in comparison to the reference method ranged from 8 to 15%, reaching statistical significance for the best jump score ($p < 0.001$).
CONCLUSION: There are significant differences between final LESS score based on the calculation method. Since the calculation method can influence group mean LESS scores, group-level risk categorisation, and individual-level risk categorisation; using a consistent LESS protocol is recommended, and comparing studies using different methods should be done with caution.

-> EFFECT OF FUNCTIONAL PILLOW ON POSTURAL BALANCE, FUNCTIONAL MOVEMENT AND FOOT PRESSURE

YUN, S.1, LEE, H.1, LIM, D.1, HWANG, E.1, SHIN, K.C.2, HA, D., LEE, D.T.1

1: UNIVERSITY OF KOOKMIN, 2: CHEIL ORTHOPEDIC HOSPITAL, 3: S&J SPACE CO,.LTD

INTRODUCTION: Recently, people using functional pillows (FP) are increasing. Pillows are traditionally a sleeping goods, but FP has been introduced as a accessory product for pain relief and rehabilitation. Previous studies have shown that the FP relieves headache, stabilizes the cervical region, and relaxes the muscles (Cho et al. 2011; Persson, 2006). The purpose of this study is to investigate the effect of FP upon three body locations on postural balance, functional body movement, and foot pressure.

METHODS: Sixteen adults participated in the study (8 men; 36.3±10.9 yrs, 76.2±7.2 kg, 174.6±2.8 cm, 25.1±2.7 kg/m2, 8 women; 40.1±13.5 yrs, 57.9±6.8 kg, 158.6±4.5 cm, 23.0±3.0 kg/m2). Before the study, their range of motion (ROM) in the neck, shoulder, waist, hip, knee and ankle was measured, and Functional Movement Screen (FMS) was evaluated by a technician. Flexibility (seat-and reach and back extension in cm) and foot pressure (MS9705, Kitronyx, Koea) were also measured. For the test, they rested in a supine position while lie down on three pillows (neck, waist, and ankle) (Dr. Shin Pillows, Korea) simultaneously for 30 min. After the pillowing, their ROM, FMS, flexibility and foot pressure were re-examined. The paired t-test was performed to verify the differences between pre- and post-test.
RESULTS: The difference of right and left external rotation of shoulder and hip joint was reduced significantly from 3.5±16.1° and 4.0±3.1° to 0.6±3.9° and 2.7±2.3°, respectively ($p<0.05$), after the use of pillow. After the use of pillow, ROM of shoulder extension (55.2±6.3° vs. 51.3±13.4°), neck extension (29.9±7.6° vs. 27.3±8.4°), and hip joint flexion (129.7±14.7° vs. 121.6±11.0°) was increased significantly compared to the baseline ($p<0.05$). The FMS score was greater after the pillow use (14.1±3.9 unit) compared to the baseline (12.6±1.8 unit) ($p<0.001$). The foot pressure difference between right and left sides tended to be decreased after the use of pillow, but not significant statistically.
CONCLUSION: Based on the results, the simultaneous use of FP upon neck, waist, and ankle helped to adjust body balance and facilitate bodily movements. The FP for three locations can be suggested as a health promotion tool as it can maintain body posture and modify functional movement.

EFFECTS OF MASSAGE AND COLD-WATER IMMERSION AFTER AN EXHAUSTIVE RUNNING SESSION ON RUNNING ECONOMY AND BIOMECHANICAL PARAMETERS: A RANDOMIZED CONTROLLED TRIAL

DUÑABEITIA, I., GIL, J., ARRIETA, H., RODRIGUEZ-LARRAD, A., GIL, S.M., IRAZUSTA, J., BIDAURRAZAGA-LETONA, I.
FACULTY OF MEDICINE AND NURSING

INTRODUCTION: Despite the growing body of literature regarding the effects of different recovery interventions on fatigue1, it remains unclear how efficiently these interventions affect running economy (RE) and biomechanical parameters in runners. Thus, this study aimed to compare the effects of massage and cold water immersion (CWI) for enhancing recovery and alleviating fatigue after an exhaustive running session.
METHODS: We performed a randomized controlled trial to analyze the effects of massage and CWI on RE and biomechanical parameters in well-trained male runners (n=48) following a standardized exhaustive running session. Each participant attended the laboratory on two occasions. The first session was performed to obtain baseline measurements 24-h after the exhaustive running session and included anthropometrical measurements and a treadmill speed test to determine RE and biomechanical variables, such as stride length, height, angle, frequency and ground contact and swing time. One hour after this test, subjects either received massage treatment (40-min), CWI treatment (10-min, 10°±0.5°C) or rested passively in a sitting position for 30-min. Twenty-four hours after the recovery intervention runners repeated the treadmill speed test.
RESULTS: At 14 km•h-1 massage group significantly decreased RE ($p<0.05$). In addition, this decrease was significantly greater than the observed in the passive rest group ($p<0.05$, $\mu2=0.17$).
At 16 km•h-1, greater swing times, stride heights, and angles ($p<0.05$) were observed in the massage group after the intervention. Moreover, stride height and angle increases were significantly greater than those observed in the CWI and passive rest groups ($p<0.05$, $\mu2=0.16$-0.20 and 0.13-0.16, respectively).
No differences were observed between CWI and passive rest groups.
CONCLUSION: The results of this study suggest that massage seems to be a more effective recovery modality for RE and biomechanical parameters following an exhaustive running session compared to passive rest and CWI. Choosing the best post-exercise recovery technique becomes difficult for athletes as very few studies compare the impact of the different recovery interventions; therefore, our results may have important performance implications for recovery optimization in runners.

MUSCLE FATIGUE IN THE MUAY THAI TRAINING

MAGNANI, S., MULLIRI, G., PINNA, V., ROBERTO, S., GHIANI, G., MOCCO, A., CRISAFULLI, A.
UNIVERSITY OF CAGLIARI

INTRODUCTION: Muay Thai is an ancient martial art. In previous studies it was classified as an intermittent physical activity, with of aerobic and anaerobic metabolism recruitment (1). It has been shown that on average matches are performed at an intensity above that of anaerobic threshold (AT). During a match, fatigue can be quantified as a decline in the maximal force or power output (PO) of a muscle. Thus, during exercise bouts performed above AT, fatigue can cause reduction in PO of the muscle involved in that exercise (3). The aim of this study was to evaluate whether a training session which simulated a typical Muay Thai attack phases was able to induce sign of fatigue on lower limbs musculature.
METHODS: 10 male Muay Thai fighters (age 27.8 ± 5.1 yrs, height 174.6 ± 6.7 cm, body mass 70.5 ± 8.9 kg) agreed to participate in the present study. Bio-mechanical parameters related to legs PO were collected at the beginning (PRE T) and at the end (POST T) of a simulated Muay Thai attack training session consisting in 3 rounds lasting 3 minutes and spaced by 1 minute of recovery. By employing a wearable inertial measurement unit (FreePower, Sensorize, Rome, Italy), the following parameters were obtained: maximum height of jump (MJH), peak force (PF), peak power (PP), peak velocity (PV), and stiffness index (SI). Heart rate (HR) was also collected with a chest belt (H7, Polar, Kemple, Finland) at PRE T, throughout rounds and at POST T. Statistics was carried out with paired the t -test (level of significance: $p<0.05$).

RESULTS: No significant difference was found in any bio-mechanical parameters between PRE T and POST T. HR was significantly higher in the POST T (142±13.5 bpm) compared to the PRE T (80±11 bpm). No difference was found between rounds (1st round 171±11 bpm, 2nd round 175±10 bpm, 3rd round 175±10 bpm) .
CONCLUSION: Our study shows that a high-intensity training session similar to a real match does not induce any reduction in legs PO in Muay Thai athletes. This notwithstanding the high cardiovascular activation, as testified by HR behaviour, which increased up to 90% of theoretical maximum during the 3rd round. These findings suggest that the fitness level of studied athletes sufficed to support the muscle requests thereby avoiding any detectable sign of muscle fatigue or PO reduction.

RELATIVE OVERHEAD PRESS CORRELATES WITH JAB PUNCH VELOCITY, BUT NOT CROSS PUNCH VELOCITY IN MALE BOXERS

PÁDECKÝ, J., KUBOVÝ, P., JEBAVÝ, R., TUFANO, J.J.
FACULTY OF PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY

INTRODUCTION: Although many different boxing punches exist, two of the most common are the straight cross and the jab. As resistance-training is a common practice among boxers, it could be useful to know if some exercises should be prioritized over others when aiming to improve punch velocity. Although the arm adductors are used during punching, it can be argued that straight punches more heavily rely on movements initiated by the legs, culminating with shoulder flexion and elbow extension. Therefore, the purpose of this study was to determine how well overhead pressing strength (OHP) correlates with peak velocity (PV) during jab (JAB) and cross (CROSS) punches in male boxers.
METHODS: Twelve elite male amateur boxers (BM 80,4±11,1 kg, height 181,6±7,1 cm, boxing experience 8±5,9 years) participated in this study, which took place over two laboratory visits. During the first visit, subjects performed a warm-up and completed OHP one repetition maximum (1RM) testing using a standard progressive loading test. During the second visit, which occurred approximately 24 hours later, subjects completed a general warm-up followed by a boxing-specific warm-up that included 5 minutes of rowing, mobility drills and three shorts boxing sprints with increasing intensity on the heavy bag. After 4 min of rest, subjects performed 5 JAB and 5 CROSS punches in randomized order with approximately 3 s in between each. Punches were tracked with the Qualisys Motion Tracking Manager (QTM), where the marker used for measuring PV was placed in the middle of 12 oz gloves. The greatest PV from the 5 punches of each type was then used for later analyses. Pearson's correlation coefficient was used to calculate correlations between absolute and relative OHP overhead press and PV during the JAB and CROSS.
RESULTS: OHP 1RM was 59.58 ± 6,895 kg, resulting in a relative OHP 1RM of 0.75 ± 0.076. JAB PV in mm/s was 8499,30 ± 509,323 and CROSS PV was 9793,80 ± 729,976. There were small correlations between either absolute OHP and CROSS PV (r = 0.4237; r2 = 0.1795) or absolute OHP and JAB PV (r = 0.3475; r2 = 0.1208). There was a small correlation between relative OHP and CROSS PV (r=0.3664; r2=0.1342), but there was a high correlation between relative OHP and JAB PV (r=0.7955; r2= 0.6328).
CONCLUSION: The high correlation between relative OHP and JAB PV indicates that the JAB may be a more upper body dominant movement than the CROSS, which displayed a much lower correlation to relative OHP strength. Therefore, if a boxer aims to increase their PV during the JAB, increasing relative OHP strength would likely be warranted. On the other hand, if a boxer aims to increase PV during a CROSS, it may be that increasing a combination of lower body strength, trunk rotational strength, or shoulder adductor strength both may be more important.

DIFFERENCES BETWEEN MALE AND FEMALE WRESTLERS IN THE EFFECTIVENESS OF SET UP ON LEG ATTACK SUCCESS

ITO, S.1, KANOSUE, K.2
WASEDA UNIVERSITY (1), (2).

INTRODUCTION: Wrestling competitions utilize weight classes, and many wrestlers cut weight before matches. Body composition and lean body mass do not differ between elite and sub-elite wrestlers (1). Therefore, wrestlers must depend upon skill and physical ability to win matches. The leg attack is the most basic and important skill in free-style wrestling (2). To execute a leg attack against a quality opponent, the balance and anticipation of the adversary must be disrupted. This can be accomplished in many ways, which include fake attacks, and changes in tempo or speed. In Judo, this disruption is referred to as kuzushi or "balance breaking". English speaking wrestlers usually refer to it as "set up". In the sport of volleyball, an analysis of the statistics showed that the factors that determined match success differed by gender (3). Based on our experiences in both wrestling teaching and competition, we thought that different genders have dissimilar strategies immediately before attempting a wrestling leg attack. The purpose of this study was to clarify the influence of set up on the success rate of leg attacks, and to determine whether or not a gender difference existed.
METHODS: For males, we analyzed video recordings of 57 matches from two international competitions. For females, we analyzed 58 matches from two international competitions. The following aspects were analyzed: (Ⅰ) whether the wrestler utilized set up or not, (Ⅱ) the result （success or failure） and (Ⅲ) the score awarded for the leg attack. To examine the connection between set up and each element, we performed a chi-square test.
RESULTS: In males there were statistically significant correlations between the presence of set up and success of the leg attack as well as the presence of set up and the score awarded for the leg attack. However, in females there was no significant correlation with either relationship.
CONCLUSION: Our findings indicated that set up improved the success rate of leg attacks. This likely occurred because set up disrupted the opponents defense as a result of altering the opponent's balance, concentration, and/or movement direction. However, a similar relation was not seen for the females. In general, males are superior to females in the physical characteristics that are important for wrestling (4). Also, differences in the competition levels might have affected the results. Men's wrestling has a longer history than does women's wrestling, so strategies and tactics in the women's matches might be still be at a lower level. The present results suggest that set up immediately before a leg attack improves the success rate for men but not for women. Different approaches may be required for men and women when teaching how to perform a leg attack, as well as how to set up an opponent for a leg attack.

SPECIFIC TEST AND STANDARDS FOR DETECTING THE RESPONSE TIME AND THE PRECISION OF THAI AMATEUR BOXER'S PUNCHES

RIRERMKUL, P.1, POLMANG, B.1, JURARAKPONG, P.1, JAYSRICHAI, T.2, VANASANT, T.1

1: SPORTS AUTHORITY OF THAILAND 2: FACULTY OF PHYSICAL THERAPY, SRINAKHARINWIROT UNIVERSITY

INTRODUCTION: A new machine has been created for evaluating the response time and the precision of boxer's punches by SAT and SWU. As a result, the specific tests and standards for evaluation of punches in amateur boxing were created by this research.
METHODS: Thai Amateur Boxers (52 Male; mean age 18.69+4.01 yrs., mean height 167+6.46 cm., boxing experience about 3 yrs., weight divisions; 51 kg. Flyweight, 53 kg. Bantamweight and 64 kg. Light welterweight) were tested with the response time and the precision machine. Subjects were instructed to throw punch as fast as, as accurately as, and as forcefully as, they could when a face target went on the LED. The response time and precision of six specific tests (20 punch per test) which consists of Basic Punches in boxing, Jab Punch (left hand), Straight Punch (right hand), Jab-Straight-Uppercut Combo, Jab-Uppercut-Jab Combo and Jab-Straight-Jab Combo, were recorded by the new machine.Then the collected data will be used to create the standards for evaluation of the response time and the precision.
RESULTS: The standards criterion was divided into 5 levels; Excellent, Good, Average, Fair, Poor, respectively. The response time and the precision results of Basic Punches in boxing (790 ms, 46%), Jab Punch (690 ms, 40%), Straight Punch (680 ms, 45%), Jab-Straight-Uppercut Combo (460 ms, 38%), Jab-Uppercut-Jab Combo (430 ms, 39%), Jab-Straight-Jab Combo (210 ms, 35%)
CONCLUSION: The result is aligned with Chadli's (2014) and Favre et al. (2007), which indicates that touch time varied from 432 to 750 ms. The response time of Jab-Straight-Jab Combo is similar to other response time machine (hand-eye reaction time). Punch precision is important to develop punching as this result shows that long series punches (4 or more punches) was found at 35%-46%.The results of this study can be used to tests and evaluate the response time and the precision of punches in Thai Amateur Boxing.

PACKING A PUNCH: PHYSICAL STRENGTH AND POWER CHARACTERISTICS ASSOCIATED WITH DELIVERING FORCEFUL DAMAGING PUNCHES

DUNN, E.C., HUMBERSTONE, C.E., FRANCHINI, E., IREDALE, K.F., BLAZEVICH, A.J.

AUSTRALIAN INSTITUTE OF SPORT

INTRODUCTION: Delivering forceful punches is an important factor in achieving success for amateur and professional boxers. Previous research suggests that physical strength and power in the upper and lower body are all important characteristics associated with punching with great force. However, only one study explicitly examines this relationship and it is possible that heterogeneity of the participant sample may have influenced the strong relationships that were observed, and thus overestimated the importance of some physical traits for punch force production.
METHODS: This study examined the relationship between upper- and lower-body strength and power characteristics and punch performance in 28 highly-trained male amateur boxers (19 ± 2 years; height 177.3 ± 7.3 cm; body mass 70.5 ± 11.7 kg). All participants undertook standardised warm-up and familiarisation procedures before testing commenced. Punch performance was assessed with a custom-built punch integrator using a 3-min maximal effort punch test (3MPT) that contained straight- (jabs and crosses) and bent-arm punches (hooks) from the lead and rear hands. Peak punch force and force-time variables including impulse and rate of force development (RFD; calculated to various relative and absolute points) were assessed. Force, power and RFD of the upper and lower body were assessed with countermovement bench throw (CMBT), isometric bench push (IBP), countermovement jump (CMJ) and isometric mid-thigh pull (IMTP) tests.
RESULTS: Correlation and regression analyses revealed significant ($p < 0.05$) relationships between peak punch force and forces measured in CMJ and IMTP tests. Additionally, peak punch force was significantly related to body mass, however, RFD in the lower body (i.e. measured in IMTP) was not. Moreover, no meaningful relationships between punch force characteristics and any upper body strength or power parameter were identified.
CONCLUSION: The results of this study show that lower-body strength but not lower-body RFD was significantly and positively related to peak punch force production. This may be because a higher ground reaction force can be generated and thus forward momentum can be developed which can be subsequently delivered in a punch. While upper-body strength and power are expected to be important in boxing, they did not discriminate between boxers who punched with higher or lower peak force. Training that improves lower-body strength without increasing total body mass (to maintain weight category) may positively influence punch capacity in highly-trained amateur boxers.

FACTOR STRUCTURE OF GENERAL MOTOR AND KARATE SPECIFIC FITNESS TESTS IN MALE KARATE ATHLETES

HEAZLEWOOD, I., KESHISHIAN, H.

CHARLES DARWIN UNIVERSITY

INTRODUCTION: Motor and sport specific fitness tests are applied in sport to evaluate athlete potential, in talent ID and responses to training. However, multivariate approaches to understand the more complex interactions of fitness factors in sport either general or specific, such as anthropometrics, strength, power, flexibility, speed and reaction time are rarely evaluated, such as how many factors should be measured to provide sports specific information. How karate specific tests map or correlate with general motor fitness is largely unknown. Some research on male karate athletes, using small samples and ability levels (elite vs novice) provided some insights, and recommended replication of this type of study, increased sample sizes and more heterogenous samples to assess factor structure stability (1). The aim of the research was to implement previous research recommendations to assess factor structure of general motor and sport specific fitness tests with male karate athletes.

METHODS: Ninety-six male karate athletes in the study. Ability levels elite (black belt), intermediate (2-3 years experience non-black belt) and novice (training 1-3 months). Data collected in sports science laboratory and included age (not in analysis); general motor fitness variables of height, weight, resting heart rate, standing long jump, isomeric hand grip, arm crank, sit-reach ROM and dynamic balance. Karate specific variables were punch force, punch speed 100cm, punch reaction time 10cm, karate agility and seated abduction ROM. Karate specific tests designed by professional karate coaches (Delphi method) (1). Exploratory factor analysis applied where researchers have no preconceived model for factor structure (2). Principle component analysis applied, Eigen values >1 representing significant factors, factor loadings > 0.5 for each variable as significant, and orthogonal rotations to assess different factor structures (2).
RESULTS: Different fitness variables related to factors were; factor 1 with punch force (.746), arm crank (.845), long jump (.790), karate flexibility (.532) and general flexibility (.813); factor 2 with karate agility (.769), punch response reaction time (.693), punch speed 100cm (.718), balance (-.615) and karate flexibility (-.591); factor 3 with height (.737), weight (.896) and isometric handgrip (.773) and factor 4 with resting heart rate (.941).
CONCLUSION: Findings indicate general and karate specific factors are related in a multivariate context where factor 1 and factor 2 associated with karate specific and general concepts. Factor 3 and factor 4 represent general motor fitness concepts. Possibly an outcome of karate athletes training for both karate specific and general motor fitness to enhance force, power, speed, agility and flexibility.

PHYSIOLOGICAL AND KINEMATIC RESPONSE TO TAEKWONDO-SPECIFIC EXERCISE IN ELITE MALE ATHLETES

JANOWSKI, M., ZIELINSKI, J., KUSY, K.

POZNAN UNIVERSITY OF PHYSICAL EDUCATION

INTRODUCTION: Taekwondo is a demanding combat sport that is undergoing constant rule. These changes result in increased combat intensity, intensified exercise response and longer post-combat recovery (1). Recent research suggests that high-intensity interval training (HIIT) is an exercise form that effectively prepares taekwondo athletes for increased requirements (2,3). However, proposed exercise tasks within HIIT are not taekwondo-specific (running or cycling). The aim of this study was to show the physiological and kinematic response to taekwondo-specific exercise within a HIIT training programme, in comparison with values achieved during laboratory progressive cardiorespiratory treadmill test until exhaustion.
METHODS: Elite male taekwondo athletes were monitored for one year (n=10, age=20.2±2.78). In total, 216 exercise circuits were monitored (21.6±4.79 circuits per athlete). A bio-monitor (Bioharness™ 3, Zephyr Technologies, USA) was utilized for kinematic and physiological data gather. Each athlete underwent blood sampling before and after exercise for lactate concentration. Training sessions consisted of taekwondo-specific tasks being part of a HIIT programme. One session had 3 circuit sets of 3 series of 8 minute exercise bouts with a 2:1 work to rest ratio. An analysis of variance (ANOVA) for repeated measures was applied.
RESULTS: All of the circuits were carried out on an average intensity level of 93.8±5.2% HRmax when comparing to laboratory tests. There were also differences regarding consecutive circuits: 90.9±4.6% HRmax for the first, 93.7±4,3% HRmax for the second, and 97.0±4.9% HRmax for the third one. Other important factors differentiating the circuits were peak mechanical activity (first 18.6±1,4 m·s-2, second 19.2±1,7 m·s-2 and third 20.1±1.6 m·s-2), average mechanical activity (first 11.2±0.8 m·s-2, second 11.7±0.6 m·s-2 and third 12.1±0.9 m·s-2), energy expenditure (first 14.1±2.5 kcal·kg-1·h-1, second 17.9±2.0 kcal·kg-1·h-1and third 19.8±2.3 kcal·kg-1·h-1), lactate concentration (first 6.9±1.0 mmol·l-1, second 9.8±1.5 mmol·l-1 and third 12.8±1.3 mmol·l-1) and %LAmax (first 79±16%, second 111±20% and third 147±25%). All p-values for between-circuit differences were less than 0.001.
CONCLUSION: The gather data indicates that a dedicated taekwondo-specific exercise within a HIIT training programme results in strong exercise (mechanical and kinematic) response. The exertion measured does replicate (and even exceeds) maximal stress present in a laboratory test. It seems reasonable to incorporate high-intensity taekwondo-specific training tasks into training programmes to maximize exercise response as a means to prepare elite athletes for the increasingly demanding competition. 1) Janowski et al. THE WINGATE TEST IN THE DIAGNOSIS OF THE TRAINING IN JUDO

GABRYS, T.1,2, CHARVAT, L.1, SZMATLAN-GABRYS, U.3

1: UNIVERSITY WEST BOHEMIAN PILSEN CZECH REPUBLIC 2: JAN DLUGOSZ UNIVERSITY CZESTOCHOWA, POLAND, 3: UNIVERSITY OF PHYSICAL EDUCATION, KRAKOW, POLAND

INTRODUCTION: The effort of judokas during competitions, and most of the training sessions, is anaerobic, and based on interval work. Work of such nature is done in all training periods. Diagnosis in this field is an important element of the evaluation of the plan of the carried out training sessions, as well as of the readiness to undertake the efforts specific to this sports discipline. (Franchini et al. 2011) The aim of the study, was the evaluation of the changes of values, and of the nature of the relations among Wingate Test indicators during the annual cycle of training of judokas.
METHODS: The study group included 18 judokas (aged 18-21, training experience 6-12 years). They participated in training sessions amounting to 1,5-5 hours a day for 10 months. They carried out 5-11 training sessions a week. According to a Wingate Test (Szmuchrowski et al. 2013) the study group carried out the efforts on cycloergometer Excalibur (Lode). Indicator values: Pmax – max power [W/kg], Wtot-total work [J/kg] PD- power degree [%], were calculated in relation to the body weight of the judokas.
RESULTS: The diagnosis of anaerobic capacity was carried out before the beginning of general preparation, (GP1, and GP2), and special preparation (SP1, and SP2) the two cycles of a period encompassing one year. The statistical analysis of Wtot, Pmax , and PD, demonstrated statistically significant changes in the values of these indicators. Wtot decreased from 274.18±20.43 to 266,16 ±22.84 J/kg of body weight after GP1. The return to the GP1 level occurs after SP1. During SP2, Wtot increased from 265.36±22.81 to 278.55±19.85 J/kg of body weight. After SP2, WTOT reaches the level of 288.16±17.93 J/kg of body weight After GP1 , Pmax decreases from 11.95±0.93 to 11.47±0,99 W/kg. (p=0.05) Between GP1 and SP2, Pmax increases by 0,93 W/kg of body weight. The highest Pmax value was registered during GP2, and SP2: 12.12 and 11.38 W/kg respectively. After GP2, PD value decreased in relation to SP2. The decrease was statistically significant (p=0.05), from 24.44±2.49 to 23.21±2.64%. In all training periods, there is a highly statistically significant correlation between the values of Wtot, and Pmax (p=0.001)
CONCLUSION: In all training periods, there is a highly statistically significant correlation between the values of Wtot, and Pmax. However, there is no statistically significant correlation between the values of PD, and Wtot.. The above-mentioned relations among the values registered in the Wingate Test, indicate to the conditioning of the value carried out during the 30-second total work, by the value of the

total power. The outcome of the correlation analysis of the Wingate Test results, indicates that the preparation as to the possibility of developing maximum power, and, indirectly, strength, and velocity training, are decisive for the anaerobic capacity levels of judokas

ROWING BUT NOT MULTIMODAL HIGH-INTENSITY INTERVAL TRAINING REDUCES ALANINE TRANSAMINASE AND ASPARTATE TRANSAMINASE IN YOUNG ADULT FEMALES

BROWN, E.C., RENGERS, T.A., ELSESSER, M.A., ORR, S.C., TYLER, R.T., ESCHKER, E., HEW-BUTLER, T., MARKS, C.R.C., CHOI, M.D., BUTCHER, S.J., DRIGNEI, D.

OAKLAND UNIVERSITY

INTRODUCTION: While high-intensity interval training (HIIT) has resulted in improvements in a range of cardiometabolic outcomes in obese adults (Batacan et al., 2016), a paucity of studies exist that have investigated these effects in non-obese adults. Also, as multimodal HIIT using strength training and aerobic exercises is becoming more popular in fitness gyms, it is important test how this type of training compares to more traditional HIIT using aerobic exercise. Thus, the aim of this study was to determine the effects of rowing HIIT (R-HIIT) and multi-modal HIIT (MM-HIIT) on cardiometabolic outcomes in non-obese females.
METHODS: Non-obese females (n=19, 22.8±5.3 years) were randomized into a MM-HIIT or R-HIIT group. At pre- and post-intervention, participants were assessed on the following variables: height, weight, waist circumference (WC), resting heart rate, blood pressure, total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, triglycerides, glucose, alanine transaminase (ALT), and aspartate transaminase (AST). The 12-week HIIT intervention included three 1-hour sessions a week. In order to determine group differences at baseline, an independent samples t-test was conducted. To examine differences between groups at post-intervention after controlling for baseline values, WC, and waist-to-height ratio (WHtR), an analysis of covariance (ANCOVA) was used with the Bonferroni post hoc comparison to determine significant treatment differences. Significance level was set a priori at 0.05.
RESULTS: Sixteen participants (R-HIIT: n=7; MM-HIIT: n=9) completed the intervention. Results from the ANCOVA showed a significant group effect for ALT (mean difference=-13.16, P=0.01, effect size (ES)=0.44, confidence interval (CI)= -22.92 to -3.40) and AST (mean difference=-10.79, P=0.02, ES=0.38, CI= -19.90 to -1.67) such that the R-HIIT group decreased significantly more than the MM-HIIT group in each of these outcomes. No other changes were found.
CONCLUSION: R-HIIT was more effective in reducing both ALT and AST values in young adult women compared to MM-HIIT, thus reducing cardiometabolic risk. These improvements are consistent with results from Oh et al. (2013) who found a decrease in ALT of -8.8 U/L in obese men after a 12-week aerobic and resistance training intervention, and with findings from Keating et al. (2015) who found a decrease in AST in overweight adults after completing an 8 week aerobic intervention. These findings suggest that traditional aerobic-based HIIT can be an effective preventative method for reducing cardiometabolic risk in young adult females.

TYPE 2 DIABETES ELICITS ELEVATED OXYGEN CONSUMPTION AT MAXIMAL RELATIVE FAT OXIDATION AND AT THE GAS EXCHANGE THRESHOLD IN AGING WOMEN.

PAQUIN, J., MONY, M.M., MARCOTTE-CHÉNARD, A., DIONNE, I.J., RIESCO, E.

UNIVERSITY OF SHERBROOKE

INTRODUCTION: Type 2 diabetes (T2D) and aging are both important risk factors for cardiovascular diseases. Improving fat oxidation with exercise is essential to improve glycemic control and reduce the risk of T2D-related complications. Aerobic exercise can enhance fat oxidation when prescribed at the right intensity. In this context, moderate intensity continuous exercise (MICE) is of great interest, because of its greater acceptability and tolerance than high intensity exercise (HIE) and because it requires less, if any supervision. MICE intensity is usually close to gas exchange threshold (GET), and is known to correspond to the highest relative fat oxidation point (FATmax). Nonetheless, because exercise substrate oxidation and tolerance are well known to be altered in T2D and aging women, it is unclear if MICE, usually prescribed close to GET, can target FATmax. This study is a secondary analysis of two exercise interventions studies. The aims of the present study were to compare both GET and FATmax relative intensities (% VO2 max) between T2D and non-T2D aging women and to determine if exercise at GET intensity elicits comparable substrate oxidation in each group. Our hypotheses are that GET and FATmax will occur at higher relative exercise intensity in T2D women and that GET exercise intensity may elicits lower relative fat oxidation in DT2 aging women compared with their non-DT2 counterparts.
METHODS: Gas exchange threshold and FATmax (estimated from respiratory exchange ratio; RER) were measured by breath-by-breath gas exchange measurement (metabolic cart, Medgraphics, UK) during a maximal aerobic capacity test on treadmill (modified Bruce ramp protocol) in 26 T2D (n=10; 67.5 +/- 3.2 years) and non-DT2 (n=16; 65.1 +/- 3.2 years) women. Relative FATmax was identified as the point where RER was closest to 0.73 +/- 0.2. GET was identified from a combination of three methods: 1) ventilation kinetics; 2) V-Slope; 3) VE/VO2 and VE/VCO2 curves as well as raw data.
RESULTS: FATmax occurred at a significantly higher relative intensity in women with T2D (71.2 +/- 12.4 % VO2 max) in comparison with their non-T2D counterparts (58.4 +/- 11.0 % VO2 max) (p = 0.01) despite no significant differences in VO2 max (non-T2D: 20.2 +/- 0,85 mL/kg/min; T2D: 18.9 +/- 1.0 mL/kg/min). GET intensity difference approached statistical significance (p = 0,09) and corresponded to FATmax in both groups. (non-T2D: 65.0 +/- 11.4 % VO2 max; T2D: 72.5 +/- 12.8 % VO2 max).
CONCLUSION: The exercise intensity where FATmax, as well as GET (although not statistically significant), occurs is substantially elevated in DT2 elderly women. Our results thus show that T2D aging women may have to reach higher exercise intensity and oxygen consumption in order to optimize the use of fat as fuel. Hence, clinicians and exercise professionals should consider these differences when the goal is to maximize lipid oxidation in T2D elderly women.

EXOGENOUS CARBOHYDRATE OXIDATION RATES CAN BE ACCURATELY DETERMINED AFTER 20 MINUTES OF MODERATE INTENSITY ENDURANCE EXERCISE

PODLOGAR, T., WALLIS, G.A.

UNIVERSITY OF BIRMINGHAM

INTRODUCTION: Exogenous carbohydrate (CHO) oxidation rates are commonly determined during exercise using stable isotope tracer methods. Research participants usually ingest CHO with a known amount of isotopically labelled 13C atoms which in turn appear as 13CO2 in expired breath as a result of CHO oxidation. By knowing the amount of ingested 13C atoms, it is possible to determine exogenous CHO oxidation rates. It has been proposed that this method is only accurate after 60-min of exercise1, as at earlier time points 13CO2 can temporarily be retained within the body's bicarbonate pool prior to expiration at the mouth. Obtained values in the first 60 minutes of exercise would therefore underestimate exogenous CHO oxidation rates. This presents a problem for determination of exogenous CHO oxidation rates in studies where exercise duration is limited (e.g. less than 60 min). This study aimed to determine if exogenous CHO oxidation rates could be accurately quantified within the first hour of exercise by assessing the excretion rates of ingested 13C labelled bicarbonate as breath 13CO2 as a marker of the retention of 13CO2 within the body during exercise.
METHODS: 6 recreational cyclists took part in this experiment (4 males, 2 females; age: 33±5 years; VO2max: 56.1±2.8 mlO2·min-1·kg-1; Wmax: 5.0±0.3 W·kg-1). Participants were tested after an overnight fast. Immediately after ingestion of ~0.2 mg·kg-1 body weight of 13C labelled bicarbonate they exercised at 50% Wmax for 60 minutes. 13CO2 production, reflecting 13C labelled bicarbonate excretion was determined throughout exercise by measurement of CO2 production (indirect calorimetry) and 13CO2/12CO2 ratio (isotope ratio mass spectrometry). Cumulative excretion of labelled bicarbonate was quantified at 2, 5, 10, 20, 30, 45 and 60 minutes as previously described2.
RESULTS: Upon visual inspection of cumulative 13C excretion, 2 linear trend-lines best fitted the data. Initially, 13C excretion rose rapidly exhibiting a linear trend with a coefficient of 7.85. Thereafter, a horizontal linear trend was observed (coefficient of -0.03; i.e., a plateau), whereby it was considered to represent a point where full recovery of 13C had been reached. The interception between both trend-lines was calculated to be at 12.4 minutes, however due to variability in the data it was considered safe to propose that exogenous CHO oxidation rates could accurately be determined after the 20-min time point.
CONCLUSION: As ingested 13C labelled bicarbonate was completely recovered as expired 13CO2 within 20 minutes after administration it is concluded that exogenous CHO oxidation rates can be accurately determined after 20-min of moderate intensity endurance exercise. Thus, exogenous CHO oxidation could be measured in future studies even when exercise duration is limited to less than 1 hour.

CHANGES IN THE GUT MICROBIOTA OF HIGHLY TRAINED DISTANCE RUNNERS DURING A SUMMER TRAINING CAMP IN A HOT ENVIRONMENT

MATSUO, K.1, OKAZAKI, K.2, GOTO, K.3, ISHIBASHI, A.4, SUGITA, M.5, OYANAGI, E.1, YANO, H.1, ONODERA, S.1

1 KAWASAKI UNIVERSITY OF MEDICAL WELFARE., 2 OSAKA CITY UNIVERSITY., 3 RITSUMEIKAN UNIVERSITY., 4 JAPAN INSTITUTE OF SPORTS SCIENCES., 5 NIPPON SPORT SCIENCE UNIVERSITY.

INTRODUCTION: Endurance runners often experience symptoms similar to those of irritable bowel syndrome. These symptoms can be especially debilitating with long-distance and high-intensity running. Our questionnaire study of long-distance athletes determined that many endurance runners suffered from gastrointestinal symptoms during competition or training. During marathon training, the athletes are often exposed to hot environments over long periods, which is an increasingly important issue owing to the progression of global warming. This causes many athletes to complain of worsening bowel symptoms. Therefore, urgent action is needed to ensure appropriate conditions for the athletes during summer training and competitive races. The aims of this study were to investigate the relationship between endurance training and changes in the gut condition in marathon runners during a summer training camp and to obtain useful data for designing countermeasures for the hot environments.
METHODS: Eleven female marathon runners from Japan's national team (mean age, 24.7 years; height, 157.0 cm; weight, 44.2 kg; % body fat, 13.0 %; and VO2max, 65.9 mL/kg/min) participated in this study. Each of them was asked to provide stool samples near the start and end of the training camp for gut microbiota analysis. During the camp, the athletes trained for and completed two 30-km runs. The gut microbiota was classified by terminal restriction fragment length polymorphism analysis. Furthermore, at the time of collection of the stool samples, the athletes were asked to evaluate the form of their faeces according to the Bristol stool scale.
RESULTS: Each athlete had a different gut microbiota, although the microbiota of four of the 11 athletes showed the presence of Prevotella spp. There were no significant changes in the gut microbiota between the samples taken near the start and end of the camp, except in one athlete, who showed a remarkable change in her gut microbiota. Furthermore, nine of the athletes reported changes in their stool type to constipation or diarrhoea, according to the Bristol stool scale.
CONCLUSION: The marathon runners who attended the summer strength training camp showed no changes in the mean levels of their gut microbiota during the camp. This may be because the gut bacterial flora differed among the athletes. In addition, the gut microbiota of four of the 11 athletes showed the presence of Prevotella spp., which are more common in the people residing in Southeast Asia, which has a hot environment. This result predicted the characteristic of long-distance athletes with high competition record. We consider that this may be related to the physiological adaptation to a hot environment owing to long-duration exposure while training outside. The stool type of nine of the 11 athletes showed changes in their stool type to constipation or diarrhoea, suggesting the importance of appropriate water intake for the intestinal status during summer training camps in a hot environment.

EFFECTS OF ACUTE ENDURANCE EXERCISE PERFORMED IN THE MORNING AND EVENING ON 24-H INTERSTITIAL FLUID GLUCOSE LEVELS

KIM, H.K., FURUHASHI, S., FUKAZAWA, M., OKUBO, J., OZAKI, M., CHIJIKI, H., NANBA, T., ONEDA, S., SHINTO, T., TABATA, H., TAKAHASHI, M., SAKAMOTO, S., SHIBATA, S.

WASEDA UNIVERSITY

INTRODUCTION: Endurance exercise is recommended for the prevention and treatment of type 2 diabetes and obesity-related diseases. In addition, glucose tolerance and insulin sensitivity show a circadian rhythm. Therefore, endurance exercise at different times of the day

may contribute to the alteration of glucose level. However, to the best of our knowledge, little is known about the effect of acute endurance exercise on 24-h glucose levels. We aimed to determine whether acute endurance exercise at two distinct times of the day would have differing effects on 24-h interstitial fluid glucose levels in a healthy young men.
METHODS: Five healthy male participants aged 22.2 ± 0.4 years (mean ± standard error) performed acute endurance exercise in the morning (0900–1100 h) on one day and then in the evening (1600–1800 h) on another day, with an interval of at least 2 weeks between each trial. In both the morning and evening trials, the participants walked for 60 minutes at approximately 60% of the maximal oxygen uptake (VO2max) on a treadmill. On the day of the trials, all the participants ate the same diet 2 h before exercise. Blood samples were collected to determine blood glucose and insulin levels before exercise and immediately and 1 hour after exercise completion. Continuous glucose monitoring was used to evaluate the 24-h interstitial fluid glucose levels. Interstitial fluid glucose levels were evaluated from exercise implementation day to the next day for both trials. All the participants were instructed to maintain their usual daily dietary, sleep, and physical activity patterns during the entire study.
RESULTS: The heart rate before and during the exercise did not differ significantly between the morning and evening trials. Morning exercise showed a more desirable 24-h interstitial glucose fluctuation on the next day than evening exercise. On the other hand, the calculated area under the curve was lower in the evening trial than in the morning trial, but the difference was not significant. This research is ongoing, and we plan to conduct further detailed study in the future.
CONCLUSION: Evening endurance exercise may have a favorable effect on the interstitial glucose fluctuation on the next day as compared with morning endurance exercise.

EFFECTS OF HIGH INTENSITY INTERVAL TRAINING (HIIT) AND RESISTANCE TRAINING ON PLASMA ANTIOXIDANT ACTIVITY

FUSI, J., INNOCENTI, A., CERRI, E., DANIELE, S., MARTINI, C., GALETTA, F., FRANZONI, F.

VAT N. IT00286820501 UNIVERSITY OF PISA

INTRODUCTION: The positive effects of regular exercise on modulation of redox homeostasis have been widely demonstrated. However, the modulation of oxidative stress by regular exercise is very complex, depending on the intensity, duration and typology of exercise. The aim of our study was to investigate the plasma antioxidant activity chronic adaptation related to specific training as aerobic High Intensity Interval Training (HIIT) and Resistance Training (RT).
METHODS: The study population included 15 young male performed aerobic HIIT by 2 years (mean age 33.4±6.7 years), 15 male performed resistance training by 2 years (mean age 63.6±6.1 years) and 15 age- and sex-matched healthy sedentary subjects. Blood samples, for plasma antioxidant evaluation, were collected following a 12-h overnight fast, and after 48 hours by the last training session. Then, all subjects were underwent to anthropometric evaluation. Plasma antioxidant activity was evaluated by TOSC assay.
RESULTS: There were no differences on weight ($p>0.5$), height ($p>0.5$), BMI ($p>0.5$) and age ($p>0.5$) each group. HIIT and RT groups had lower fat mass than sedentary controls ($p<0.05$; $p<0.001$). According to plasma antioxidant activity, HIIT group showed a higher plasma antioxidant activity against peroxyl radicals than the sedentary group (23.21±2.17 vs 16.45±4.23; $p<0.001$) and RT group (23.21±2.17 vs 19.22±2.48; $p<0.01$). RT and sedentary group showed comparable anti-peroxyl activity. HIIT and RT groups showed a higher plasma antioxidant activity with respect to the sedentary group (6.14±1.40 vs 3.60±2.65; $p<0.01$) (5.46±0.76 vs 3.60±2.65; $p<0.001$). The correlation analysis showed a positive relationship between the increase of free fat mass was related both HIIT ($p<0.01$) and RT ($p<0.001$) group.
CONCLUSION: HIIT induces an increase of anti-peroxyl and hydroxyl plasma activity with respect to sedentary group. In addition, RT caused a positive adaptation only towards hydroxyl radical. These data confirm the need to perform a multidisciplinary activity even of high intensity rather than resistance exercise in order to achieve a completely protection against free radical species.

EFFECTS OF BODY FAT PERCENTAGE ON MAXIMUM POWER, FATIGUE INDEX AND BLOOD LACTATE CONCENTRATION IN TWO CONSECUTIVE WINGATE TESTS.

CASTAÑEDA, A., SANTISTEBAN, A., COCA, A.

UNIVERSIDAD DE DEUSTO

INTRODUCTION: Shorter recovery duration plays a decisive role in short-term high-intensity exercise in elite athletes. The nature and duration of intervening recovery periods determine the ability to produce and maintain high power output during successive sprints required in many sport events (Glaister, 2005; Glaister et al., 2005). Intermittent high-intensity sprint efforts combined with short recovery periods have been identified as a key factor in physical performance (Jones and Cooper, 2014).
PURPOSE:
The aim of this study was to evaluate the effects of body fat percentage on the maximum relative power (MP), the fatigue index (FI) and the blood lactate concentration ([La]) and how these variables relate to each other in two consecutive Wingate anaerobic tests.
METHODS: A group (n = 129) of CrossFit athletes (age 32.3±5.8, weight 73.3±11.9 kg, height 173.3±8.3 cm, body fat 15.6±6.2%), after performing a standard warm-up, carried out two supra maximal 30sec "all out" tests, with a rest time between them of 5 min (passive rest). The MP and FI of each test and [La] 5 minutes after the completion of each test were measured.
RESULTS: There were significant ($p < 0.05$) differences between the values obtained in the second test and the first test in the MP and [La], however there were no significant differences in the FI ($p= 0.2$). We selected the 35 CrossFit athletes (age 31.9±4.8, weight 73.6±13.4 kg, height 175.7±9.0 cm, body fat 9.06±2.8%) with less body fat percentage and the same differences were maintained. There are no significant differences in any variable between the mean of the whole group and the selected group with less body fat percentage.
CONCLUSION: These findings suggest that body fat percentage is not influential in the MP, FI or [La] obtained in two consecutive Wingate tests performed by CrossFit athletes. More research is needed to find out the reasons why there is no greater differences, suggesting that genetics may be an important aspect to evaluate in this type of tests.

IMPACT OF WEARING COMPRESSION GARMENT STOCKINGS ON HEMODYNAMICS IN LOWER LIMBS DURING PROLONGED SITTING

HORIUCHI, M., KIRIHARA-HANDA, Y.
MT. FUJI RESEARCH INSTITUTE

INTRODUCTION: It has been reported that acute prolonged sitting increases possible risk of blood clots in the lower limbs, leading to deep vein thrombosis (DVT) and followed by pulmonary embolism, otherwise known as economy class syndrome (occurrence of DVT in air travelers) (Feltracco et al. 2007). For surgical patients, compression garment stockings (CGS) have been used to prevent DVT, due to an increase of blood velocity in the veins, resulting in reductions in venous blood pooling in the lower limbs (Agu et al. 1999). However, the effect of wearing CGS on hemodynamics in the leg vasculature during acute prolonged sitting remains unclear.
METHODS: Eleven young healthy males with a mean age of 21 years, height of 170 cm, and body mass of 65 kg participated in the present study. They completed three hours of prolonged sitting with or without CGS. Heart rate (HR) and beat-by-beat blood pressure (BP) were continuously measured for 5 min at ~10 min (baseline), 1 h, 2 h, and 3 h into the sitting period. Total hemoglobin (Hb) as an indicator of blood volume at the left mid gastrocnemius muscles was measured every 1-s throughout the sitting period by near-infrared spectroscopy. Calf circumference was measured before and after sitting.
RESULTS: While there were no significant differences in HR at baseline (68 ± 6 bpm without CGS vs. 67 ± 7 with CGS, P = 0.554), a 3-h sitting without CGS significantly increased HR more than with CGS (77 ± 8 bpm without CGS vs. 71 ± 9 with CGS, P = 0.042). In contrast, there was no difference in mean arterial BP between the conditions (80 ± 8 bpm without CGS vs. 80 ± 11 with CGS at baseline, and 83 ± 11 bpm without CGS vs. 82 ± 9 with CGS at 3-h, all P > 0.05). Wearing compression garment stockings could prevent an increase in relative changes in total Hb and calf circumference from baseline to 3-h (Total Hb: Δ26.2 ± 23.1% without CGS vs. Δ14.5 ± 20.7% with CGS, P = 0.042, and calf circumference: Δ0.93 ± 0.52 cm without CGS vs. Δ-0.19 ± 0.22 cm with CGS, P < 0.001). Changes in total Hb between baseline and at 3-h were positively associated with changes in HR between baseline and at 3-h when the data of both conditions were pooled [r = 0.523, n = 22 (two conditions × 11 participants), P < 0.05].
CONCLUSION: A greater increase in total-Hb in the lower limbs without CGS may indicate a greater blood pooling in the vein. Additionally, as mean arterial BP is calculated by multiplying the stroke volume by HR via total vascular resistance, lower HR with CGS may suggest that venous return to the heart was well maintained. These findings indicate that wearing of CGS may have beneficial effects in the lower limbs during prolonged sitting.

METABOLIC RESPONSES TO A MAXIMAL EATING OCCASION

HENGIST, A., EDINBURGH, R., DAVIES, R.G., WALHIN, J.P., JAMES, L.J., ROGERS, P.J., AFMAN, G., GONZALEZ, J.T., BETTS, J.A.
UNIVERSITY OF BATH; LOUGHBOROUGH UNIVERSITY; UNIVERSITY OF BRISTOL; WESTMONT COLLEGE

INTRODUCTION: Maintaining postprandial metabolic homeostasis is a physiological challenge, and is commonly used to determine metabolic health. Humans have the capacity to overeat yet, remarkably, no study to date has investigated metabolic responses to a maximal single occasion of overfeeding. The present study characterises the physiological responses to an occasion of maximal feeding.
METHODS: Fourteen healthy men (mean±SD, age 28±5 years, body mass 77.2±6.6 kg, body mass index 24.2±2.2 kg/m^2) completed a randomised crossover with two trials. On one occasion participants ate a homogenous mixed-macronutrient food (cheese & tomato pizza; nutrition information per 100 g: energy 284 kcal, carbohydrates 33.5 g, of which sugars 6.7 g, fat 10.3 g, of which saturates 5.5 g, protein 13.4 g) until they were comfortably full (AD LIBITUM) and on the other occasion participants ate the same food until they could not eat another bite (MAXIMAL). Blood samples were obtained at baseline, then 30-, 60-, 90-, 120-, 180-, and 240-minutes postprandial following the first bite. Serum concentrations were measured and incremental area under the curve (iAUC) were calculated for glucose, insulin and triglycerides (TAG), and area under the curve (AUC) was calculated for non-esterified fatty acids (NEFA). Data shown in results are mean ±95% confidence intervals (CI).
RESULTS: Energy intake was 1584±220 kcal following AD LIBITUM eating, which approximately doubled following MAXIMAL, to 3113±492 kcal (mean±95% CI difference 1529±458 kcal). Serum glucose iAUC did not differ significantly between trials (AD LIBITUM: 94.3±64.0 mmol/L/240min vs. MAXIMAL 127.6±49.6 mmol/L/240min, p = 0.17), whereas the serum insulin iAUC was ~1.5-fold greater following MAXIMAL (78.0±23.9 nmol/L/240min) when compared to AD LIBITUM (50.8±17.9 nmol/L/240min, p < 0.01). Similarly, serum TAG iAUC was ~1.5-fold greater following MAXIMAL (146.4±57.8 mmol/L/240min) when compared to AD LIBITUM (98.6±28.7 mmol/L/240min, p < 0.01). Serum NEFA concentrations decreased to a similar extent in both trials (time effect p < 0.01, trial effect p = 0.15, time x trial interaction effect p = 0.24).
CONCLUSION: Healthy men have capacity to eat double the amount of food required to achieve comfortable fullness. Despite this 2-fold increased energy intake, postprandial glycaemia remained tightly maintained after an initial overfeed when compared to eating until comfortably full, which is likely explained by hyperinsulinaemia. In contrast, postprandial TAG is elevated following an overfeed, but to a lesser extent than expected based on the fat content of the meal. A single meal of overfeeding is metabolically well-regulated in young, healthy men.

COMPARING CHARACTERISTICS OF MOVEMENT IMAGERY STRUCTURE IN SOCCER PLAYERS WITH CONGENITAL AND ACQUIRED BLINDNESS

MOMOSE, Y.
TOKOHA UNIVERSITY

Comparing characteristics of movement imagery structure in soccer players with congenital and acquired blindness
Momose, Y.1, Akihito Koakutsu.2, Ito, H.1,
1: Tokoha University (Shizuoka, Japan),
2: National Defense Academy of Japan (Kanagawa, Japan)
Introduction

Momose and Ito (2017a) reported that a top-level Japanese soccer player with congenital blindness could effectively use movement imagery (including objective, spatial, internal, and overlooking imagery). However, the differences in the movement imagery generation structures of players with congenital and acquired blindness are unclear. Therefore, the present study compared the characteristics of movement image structures in soccer players with congenital and acquired blindness.
Methods
Participants included one Japanese soccer player with congenital blindness and another with acquired blindness. The two players were male athletes belonging to the same team. Interviews were conducted to explore the image structure of an aggressive soccer situation. Data were analyzed using Personal Attitude Construct (PAC) analysis.
Results
The soccer player with congenital blindness could imagine the elements necessary for attacking based on the tone of the ball and actions of players from his and the opponent team. On the other hand, the image of the player with acquired blindness was unclear because the imaging referenced his past memories before losing his eyesight.
Discussion
The present results suggest that the soccer player with congenital blindness used object, spatial, internal, and external imagery effectively. However, the player with acquired blindness exhibited disturbed imagery owing to the confusion between past and present images. Thus, coaches working with blind soccer players are recommended to utilize different strategies for those with congenital and acquired blindness.

MECHANICS OF EFFECTIVE PROPULSION MOVEMENTS FOR THE WHEELCHAIR SPRINT START

KIJIMA, K., KISHIZAWA, H., KATAOKA, S., KUNIMASA, Y., MAKINO, A., ISHIKAWA, M., ITO, A.
OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: The performance of the wheelchair athletes, such as racing time, has improved dramatically in recent years. To achieve further improvements of their performance, it is crucial to increase their wheelchair velocity during the start movement phase. However, studies have been carried out on the sprint start movements of wheelchair athletes on the wheeled platform but not on the ground. Therefore, the purpose of the present study was to examine characteristics of the upper extremity kinematics of the sprint start in wheelchair athletes on the ground and the relationships between changes of movements and wheelchair velocities.
METHODS: The 2 male wheelchair athletes participated in this study. One of the subjects was a finalist at the sprint event of the World Para Athletics Championships (24 yr, classification T45, "EL"), and the other was a young athlete (22 yr, classification T45, "YA"). They performed the wheelchair sprint (30m) on the official track surface and they were recorded by one high-speed camera (200fps). Each stroke of their sprint movements was analyzed with two-dimensional kinematics and then the following parameters were calculated; the velocity of the wheelchair, stroke frequency, stroke length, as well as the joint (shoulder, elbow, and wrist) and trunk segment angles and these angular velocities during the propulsive phase of the upper extremity kinematics.
RESULTS: The mean wheelchair velocities during the first stroke were 1.33 and 1.08 m/s for EL and YA, respectively. At the twelfth stroke of the upper extremity kinematics, those velocities were 6.49 and 5.61 m/s, respectively. Although their stroke frequencies did not show any relationships with increased wheelchair velocities, their stroke length was positively related to their wheelchair velocities. In the propulsion phase, the changes of the angular velocities of the shoulder flexion, elbow extension and wrist extension were positively related to their wheelchair velocities in both athletes. The angular displacements of the shoulder flexion and the trunk forward/backward rotation angles as well as their velocities of EL were significantly related to wheelchair velocities. However, the shoulder flexion angles and the trunk forward rotation displacements in YA were negative related to wheelchair velocities. The extension angular displacements of the elbow and those of the wrist in EL did not show any differences with different wheelchair velocities.
CONCLUSION: These results showed that in the start phase the velocities of the wheelchair were increased with the high forward rotation of the trunk and the shoulder flexion. In addition, EL showed the greater amplitudes of the forward rotation of the trunk and the shoulder flexion than YA. Thus, EL can effectively utilize his own mass to increase the wheelchair velocity by the enhancement of the impulse to the pushrim.

AGE-RELATED CHANGES IN PARA AND WHEELCHAIR RACING ATHLETE'S PERFORMANCES

SCHIPMAN, J., GALLO, P., MARC, A., ANTERO, J., TOUSSAINT, J.F., SEDEAUD, A., MARCK, A.
INSEP

INTRODUCTION: During the last decades, all para-athletes with disabilities have significantly increased their performance level due to technological progress and human investment, through better training or recovery protocols, medical care and nutritional monitoring. Among these elements, the athletes age is one of the determining factors in performance. The aim of this study was to investigate the effect of age on maximal performances for para-athletes and wheelchair racing athletes, scaled on able-bodied records.
METHODS: We collected 53,554 results including athlete's best performance of the year, event, age and disability classification from the International Paralympic Committee competitions between 2009 and 2017 for both female and male para-athletics and wheelchair racing disciplines for a total of 472 sport events in Track and Field (considering each impairment type for each event) and gathered the all-time able-bodied records from the International Association of Athletics Federations (IAAF) at the end of 2017. Maximal performance by age was fitted with the Moore function for each para-athletics and wheelchair racing event.
RESULTS: This study finds a similar age-related pattern in maximal performance among para-athletes and wheelchair racing athletes. The age at peak performance varies according to sex, impairment type and event and increases gradually from sprint to endurance events. The best Top 100 performances include a large age range
CONCLUSION: Para-athletes and wheelchair athletes display an age-related pattern in maximal performances, similar to able-bodied athletes. The age at peak performance increases gradually from sprinting to endurance events for para-athletes. The Top 100 best performances include a large age range suggesting that performance has probably not yet been optimized for most elite para-athletes and

wheelchair racers. The Paralympic Games of Tokyo 2020 and Paris 2024 will certainly offer exceptional performances which can still be improved upon for most of the elite wheelchair racing and para-athletes.

UNICYCLE RIDING COURSES ENHANCE MOTOR PERFORMANCE AND ATTENTION IN ADOLESCENTS WITH LEARNING DISABILITIES

LIN, W., CHANG, Y.

NATIONAL CHIAYI UNIVERSITY

INTRODUCTION: Unicycle riding is enjoyable and challenging, however, its effects on motor performance and attention in adolescents with learning disabilities remain unknown. Therefore, the aim of this study was to explore the effects of unicycle riding courses on balance, power, muscle endurance and attention in adolescents with learning disabilities.
METHODS: Sixteen junior high school students with learning disabilities were randomly assigned to experimental and control group. None of them had unicycle riding experiences before. The experimental group (n=8, 13.5 ± .5 yrs) underwent unicycle riding course 2 times a week, 45 minutes each time for 13 weeks. Control group (CG, n=8, 14.0 ± 1.3 yrs) remained normal physical education schedule without unicycle riding. All participants completed tests of balance beam walking, vertical jump, 1-minute sit-up and attention questionnaires before and after training. A two-way mixed design ANOVA (with independent measures on group and repeated measures on time) was conducted for comparing the difference of performance between the two groups before and after training.
RESULTS: Group by time interactions were found in balance beam walking (p=.041), vertical jump (p=.003) and attention test (p=.03). Main effects in time were found in balance beam walking (p=.02) and attention test (p=.03). The results also showed that the adolescents with learning disabilities had significant better motor performance and attention after 13-week unicycle riding courses when compared to pre-training. Time to complete the walking on the balance beam was improved by 12.8 ± 14.1% (p< .05), the height of vertical jump was improved by 20.2 ± 20.5% (p< .05) and the scores of attention ability was also improved after training.
CONCLUSION: It is concluded that unicycle riding courses led to improvements in dynamic balance, vertical jump and attention ability in adolescents with learning disabilities.

THERMOREGULATORY RESPONSE OF LOWER LIMB AMPUTEES IN HOT AND HUMID ENVIRONMENT

FUKUHARA, K.

HIROSHIMA UNIVERSITY HOSPITAL

INTRODUCTION: Human heat dissipation is carried out by convection, conduction, radiation, evaporation. In the hot environment, heat dissipation by evaporation is actively carried out especially by arteriovenous anastomosis at the extremities of limbs. It is thought that amputee's heat dissipation is disadvantageous due to reduction arteriovenous anastomosis and decrease of body surface area, because they lose some of the limbs. In fact, there are reports of severe heat stroke at adapted sports field for people with amputation in Japan. However, understanding of thermoregulatory responses in amputees is not sufficient. It is important to understand the thermoregulatory mechanism of the amputee in order to protect them. Therefore, in this study, we made the amputee perform the arm crank exercise for 60 minutes in a hot environment, and we investigated body temperature parameters compared with able-bodied individuals.
METHODS: Subjects were 6 able-bodied persons (AB) (age 39.3 ± 8.2 years old, height 1.69 ± 0.05 m, body weight 64.3 ± 8.6 kg, body surface area (BSA) 1.735 ± 0.10 m2), 7 lower limb amputees (LLA) (age 44.3 ± 11.1 years old, height 1.77 ± 0.06 m, body weight 71.2 ± 19.5 kg, BSA 1.759 ± 0.22 m2).The subjects exercised for 60 minutes at an exercise intensity of 60% VO2 peak using a hand ergometer in a climate chamber at 33°C 70% RH. During exercise, physiological parameter were measured.
RESULTS: In AB and LLA, respectively, rectal temperature before exercise were 37.04±0.27°C and 37.10±0.56°C; rectal temperature after 60 minutes exercise were 38.37 ± 0.51 °C and 38.22 ± 0.38°C; mean skin temperature 35.80±1.26°C and 36.26±0.22°C; femoral skin temperature (non-amputation side) were 36.47±0.58°C and 36.84±0.31°C, and no significant difference was observed in any of them. The sweating amount were 1.07 ± 0.25 kg and 1.45 ± 0.46 kg; the dehydration rate were 1.74 ± 0.51% and 2.08 ± 0.60%, and although no significant difference was observed, sweating amount per BSA were 0.62 ± 0.16 kg/m2 and 0.87 ± 0.22 kg/m2, indicating a significant difference (p<0.05).
CONCLUSION: We conducted a similar exercise for the subjects in an environment of 32°C 50% Rh, and confirmed that there is no difference in rectal temperature between AB and LLA. In this study, we set high temperature and high relative humidity environment (33 °C 70% RH) with reference to the Tokyo temperature at the time of the Tokyo Paralympic Games, but there was no significant difference in rectal temperature between AB and LLA. The mean skin temperature is not much different from the environmental temperature, so the contribution of heat dissipation by conduction is small. Therefore, in both groups, the heat dissipation reaction by evaporation was the main, and the body temperature was controlled. In the LLA group, the sweating amount per BSA was large, so it was suggested that the amputees regulate body temperature by compensated sweating. It seems there is a need to actively correct and prevent dehydration by hydration .

CHANGES OF SKIN CHARACTERISTICS AFTER AN APPLICATION OF A TOPICAL WARMING PRODUCT

STOOP, R.1,2, HOHENAUER, E.1,2,3, CLARYS, P.3, DELIENS, T.3, CLIJSEN, R.1,2,3

1: SUPSI , 2: THIM , 3: VUB

INTRODUCTION: The use of topical revulsive products are commonly used in sport and rehabilitation settings and are believed to have a hyperaemic and analgetic effect. Despite the popularity and accessability, only limited research evaluated the effects of these products. The hereby presented data are part of an extensive double-blind randomized controlled study, focussing on the physiological effects of three different warming ointments in the skin and muscle tissue. This abstract reports data of one product.
METHODS: Thirteen healthy females volunteered for this study. A total of 4 areas of interest was defined (each 10 x 10 cm) and marked on the lumbar region of the back. The intervention product (IA) was applied on the contralateral side of the control area, where a thermoneutral ointment was applied (IC). Five cm above IA and IC, untreated control areas were defined (OA and OC). Physiological outcome parameters were skin perfusion, local skin temperature, muscle oxygen saturation (SmO2) and thermal sensation. The measurements were performed at baseline (BL) and after the treatment in 5 min-intervals up to 60 min except for SmO2 (measured at BL and after 60 min).
RESULTS: Skin perfusion was significantly increased in IA compared to IC after 10 and 15 min (p=0.008, p=0.003). IA vs. OA was significantly higher after 5, 10 and 15 min (p=0.007, p<0.001, p=0.001), so was IA vs. OC after 5, 10 and 15 min (p=0.005, p<0.001, p=0.001). Skin temperature was significantly lower in IA vs. IC after 5 min (p=0.002). Skin temperature was lower in IA vs. OA (p<0.001) and also com-

pared to OC (p<0.001) up to 5 min. Skin temperature was lower in IC vs. OA (p<0.001) and IC vs. OC (p<0.001) after the treatment (0 min). SmO2 values were significantly higher in IC in comparison to OC after 60 min (p=0.019). Thermal sensation was significantly higher in IA compared to IC between 5 up to 25 min. Participants rated to feel warmer in IA vs. OA at 15 min (p=0.015) and IA vs. OC between 0 up to 25 min (p<0.05).
CONCLUSION: In conclusion, the investigated topical product enhanced skin perfusion for a short-time. Although skin temperature lowered shortly after the application, the participants felt significantly warmer in the treated area in a short and long-term. The product did not have any effects on SmO2, questionning the effect of topical ointments on muscle tissue.

INFLUENCE OF ICE SLURRY INGESTION ON CORE TEMPERATURE AND BLOOD PRESSURE DURING ACUTE RECOVERY PERIOD AFTER ENDURANCE EXERCISE IN HOT ENVIRONMENT

NAKAMURA, M.1, NAKAMURA, D.1, YASUMATSU, M.2, TAKAHASHI, H.1

1 JAPAN INSTITUTE OF SPORTS SCIENCES, 2 RIKKYO UNIVERSITY

INTRODUCTION: Quickly recovering the elevated body temperature to the pre-exercise level after exercise in a hot environment is important. Delay in the restoration of post-exercise thermoregulation has been associated with post-exercise hypotension (1). Although the effect of cold stimulation (ex. cold-water immersion) to attenuate post-exercise hypotension after the exercise has been studied, it is unclear on the effect of ingesting cold beverages on response of blood pressure after the exercise (BP). The purpose of this study was to examine the effect of ice slurry ingestion immediately after exercise on recovery of core temperature and BP.
METHODS: Seven male athletes participated in this study (age, 21.0 ± 2.0 years; height, 168.0 ± 4.5 cm; weight, 62.8 ± 4.3 kg). Subjects entered a climate-controlled chamber, with the temperature maintained at 32 °C with a relative humidity of 70%, and the subjects rested in a seated position for 20 min. After they adjusted to the environment, started running. They ran on a treadmill at 75% of their maximal oxygen uptake to exhaustion in the heat. After the exercise, subjects ingested 4 g/kg body mass of ice slurry (0.5°C, ICE condition) or control beverage (28°C, CON condition) immediately. Both the ice slurry and the control beverage used a sports drink. The subjects then recovered by sitting at rest for 20 minutes. Core temperature, BP, heart rate (HR), cardiac output (CO), and total peripheral resistance (TPR) were measured before exercise and 0, 10, and 20 minutes after running to exhaustion.
RESULTS: There was no significant difference in core temperature at the end of exercise (CON: 39.61 ± 0.6°C, ICE: 39.76 ± 0.6°C, p > 0.05) and the time to exhaustion (CON: 34.8 ± 19.3 min, ICE: 34.1 ± 12.4°C, p > 0.05) between conditions. After the ingestion of the ice slurry or control beverage, core temperature decreased significantly in the ICE condition compared with the CON condition (p < 0.05) at 20 minutes after exercise. However, no significant changes in systolic or diastolic BP, CO, TPR, or HR during recovery period were observed.
CONCLUSION: These results suggest that ice slurry ingestion after exercise promoted recovery of core temperature but did not affect BP or HR during recovery period. Further research is necessary to examination about ingestion volume of ice slurry and more long-term period after the exercise.

RELATION BETWEEN PERFORMANCE OF THE DISPLACEMENT SPEED AND BODY TEMPERATURE IN ELITE ATHLETES OF BRAZILIANS FEMALE SOCCER.

VIEIRA, N.A., REZENDE, T.M., PINHEIRO, A.M., TUONO, A.T., HARTZ, C.S., BORIN, S.H., PADOVANI, C.R., BORIN, J.P.

UNICAMP

INTRODUCTION: In female soccer, the performance in short distance speed, fundamental in the modality, has been little studied mainly when trying to understand possible associations with other variables aiming to improve performance. The skin temperature has been contributed in different studies (1, 2), to analyze physiological functions. The present study sought to associate speed performance with the difference in skin temperature of the lower limbs (quadriceps and hamstrings) in female soccer players, before and after speed test.
METHODS: Were evaluated 19 athletes from Brazilians elite female soccer (22.1±4.8 years; 1.65±0.05cm; 60.6±8.8kg and 17.0±3.8% of fat). Before the speed test, the volunteers were conditioned for 20 minutes in a room with a controlled temperature of 21ºC ± 0.3ºC. The first part of the thermal imaging protocol was the delineation of the quadriceps and hamstrings muscles. Thermal images were acquired with a thermal imaging camera FLIR® Systems Inc. Model T540, USA, and a computer (with specific software for image acquisition and processing). The images were collected immediately after the speed test. Then, was performed the velocity test at distances of 10, 20 and 30 meters according to Little & Williams (2005). After data collection it was verified the normality of the datas (Shapiro-Wilk) and then Pearsons linear correlation (p <0.05).
RESULTS: The results indicate that there was an association between: i) the performance in the 10 meters displacement and the temperature difference before and after the speed test in the quadriceps (r = -0.510, p <0.05); ii) performance in the 20 meters displacement and temperature difference before and after speed test in the quadriceps (r = -0.512, p <0.05); iii) performance in the 30 meters displacement and temperature difference before and after speed test in the quadriceps (r = -0,457, p <0.05); iv) performance in the 10 meters displacement and temperature difference before and after speed test in the hamstrings (r = -0.749, p <0.05); v) performance in the 20 meters displacement and temperature difference before and after speed test in the hamstrings (r= -0.752, p< 0.05); and, finally, vi) performance in the 30 meters displacement and temperature difference before and after speed test in the hamstrings (r= -0.712, p< 0.05).
CONCLUSION: It is concluded that the lower the execution time in 10, 20 and 30 meters the greater the difference in temperature is, both for quadriceps and hamstrings.

A STUDY OF PARAMETERS FOR THE PERFORMANCE EVALUATION OF PARA ARTISTIC SWIMMING

KAWABATA, Y.

KYOTO INSTITUTE OF TECHNOLOGY

INTRODUCTION: The objective of this study was to analyze data obtained from direct observations of Para AS performers and to explore what Para AS performers should do to enhance their performance. Para artistic swimming (Para AS) has not yet been recognized as an official competition. In order to elevate Para AS to the status of international competition, we need to raise general awareness of Para AS by encouraging people all over the world to learn about the existence of Para AS. First, however, we must understand the characteristics of the performance of Para AS. In addition to the qualitative evaluation of Para AS that has been done by researchers so far, we have also evaluated Para AS quantitatively.

METHODS: In May 2018, the 27th Para Synchronized Swimming Festival was held in Kyoto. We analyzed 11 performers who performed solo at the festival and conducted a video review by using motion analysis software, "NotePlayer2" made in our laboratory. After that, we made a quantitative evaluation of the performances of three performers with intellectual disabilities, who were the top three entries. We coded their motions at every second observed in their performance focusing on the following five points: (A) body support methods, (B) rotation or non-rotation and its direction, (C) arm movement, (D) leg movement, (E) body trunk movement. We paid special attention to items (A), (B), and (D) because they are extremely important when evaluating performance.
RESULTS: The motion analysis provided essential information regarding the ways the 11 performers used the pool, their per-second motions and movement distance, the distribution of movement speed, and the range of their movement. Concerning how to use the pool, many of the performers moved in a linear path along the long side of the pool. Movement distance was 48.1(±10.27)m on average. The range of their movement was 18.7(±3.21)m^2 on average. Top performers performed mainly with sculling, eggbeater kicks, or both as body support methods. Concerning the rotation, the first-ranking and second-ranking performers used various types of turns in their performance evenly, whereas the third-ranking performer was biased toward certain types of turns. The first-ranking performer showed leg movements from the middle to the end of the performance. The second-ranking performer used 4 more turns, and the third-ranking performer 17 more turns than the first-ranking performer respectively.
CONCLUSION: There was a high possibility that the practice environment was closely related to the fact that the performers showed linear movements in the performance of Para AS. It was suggested that the differences in the scores of the three players probably resulted from their rotations and leg movements. Based on our findings, we conclude that performance composition which takes into consideration the physical strength of a performer and the quality of his or her rotations and leg movements can lead to high scores.

BASELINE HEALTH BEHAVIORS FOR UNITED STATES MILITARY PERSONNEL PARTICIPATING IN AN EXERCISE INTERVENTION: THE ARMY TRAINING AT HIGH INTENSITY STUDY

HEINRICH, K.M.1, DEBLAUW, J.D.1, COSGROVE, S.J.1, HADDOCK, C.K.2, JAHNKE, S.A.2, POSTON, W.S.C.2
1> KANSAS STATE UNIVERSITY; 2> NATIONAL DEVELOPMENT AND RESEARCH INSTITUTES

INTRODUCTION: United States (US) military personnel are taught that good mental and physical health is imperative for their jobs, yet many choose unhealthy behaviors and rates of overweight/obesity continue to increase, as documented by the latest Department of Defense (DoD) data (1). How do health behaviors of military personnel who choose to participate in a cluster-randomized clinical trial (CRCT) exercise intervention compare to the DoD as a whole? We hypothesized that CRCT participants would report less physical activity and more unhealthy behaviors and health conditions than the DoD data.
METHODS: Participants (n=123; 77% male, 79% Army, 81% Officers, 75% white, 87% college educated, age=33.5±5.8 years, years of service=12±5, measured body mass index=26.8±3.3 kg/m2) completed a self-report survey for exercise, sport, and other health behaviors and measured height and weight
RESULTS: For activity during the past 30 days, 61.0% reported ≥150 weekly minutes of moderate physical activity, 37.4% reported ≥75 weekly minutes of vigorous physical activity, and 39.8% reported ≥3 strength training days/week. Key exercise barriers included time (60.2%) and personal/family life demands (49.6%). Common sport/exercise activities included weight-training (37.4%), running (30.1%), Army physical training (26.8%), and high-intensity functional training (14.6%); 15.4% reported no current activities. Almost all (95.9%) had passed their most recent physical fitness test. General health status was fair/good for 48.0%, and few reported high blood pressure (7.3%) or cholesterol (6.5%). More participants (58.5%) described themselves as slightly-to-very overweight, and 62.6% were trying to lose weight; 72.4% had overweight/obese BMIs. Participants reported needing 7.1±1.0 hours/night of sleep, but in the past week only had slept 6.4±1.0 hours/night. Few were current smokers (9.8%) or smokeless tobacco users (9.0%), but 33.3% reported binge drinking ≥1 day in the past month.
CONCLUSION: As compared to weighted DoD data (1), our sample had a greater proportion of Army personnel, Officers, participants ages 25-44, and women. As hypothesized, our sample reported lower rates of vigorous physical activity and strength training days/week, and higher exercise barriers, overweight/obesity, and binge drinking. However, our sample reported lower rates of hypertension, high cholesterol, smoking, and smokeless tobacco use. Rates of moderate physical activity, fitness test passage, and sleep were similar between our sample and DoD data. Some findings may be due to many participants matriculating in an advanced military school during the study, which may limit generalizability of these results to other officers and enlisted personnel. It is important to continue efforts to improve the physical activity and health of US military personnel, particularly the next generation of Army leaders.

THE INFLUENCE OF EXERCISE HABITS IN YOUNG WOMEN ON BODY COMPOSITION, MUSCLE STRENGTH AND PHYSICAL ACTIVITY.

OHTA, M.1, MITA, Y.2, TANAKA, N.3
1:CHUKYO UNIVERSITY, 2: SUGIYAMA JOGAKUEN UNIVERSITY, 3:NAGOYA UNIVERSITY

INTRODUCTION: Recent survey indicated that Japan has a low percentage of young women implementing regular exercise (1). Exercise habits to maintain sufficient skeletal muscle mass are necessary for a healthy and active life. However, the effects of exercise habits on body composition and muscle strength have not been adequately studied. Thus, this study examined the difference in body composition, muscle strength and physical activity between women with or without exercise habits.
METHODS: Subjects were 46 women aged from 20 to 39 (age: 26.1 +/- 7.6 yrs., height: 157.2 +/- 5.4 cm, weight: 52.0 +/- 7.6 kg). Using a questionnaire concerning exercise habit, we divided them into two groups: one group with exercise habits in the past or present (EH group, n = 24) and the other group with no exercise habit from past to present (NEH group, n = 22). Whole body and regional skeletal muscle mass, body fat and bone strength were measured as body composition. Grip strength, knee extension torque, back muscle strength, and the number of sit-ups in 30 seconds are correlated to assess muscle strength. We collected physical activity data for a

week while we excluded from analysis the data on days subjects exercised. A Student's t-test was used to evaluate the significance of the difference between the two groups. The significance level was set at P <0.05.
RESULTS: Body composition: There were no significant differences between the two groups, but the EH group showed lower body fat to some degree (p = 0.050). Muscle strength: There were no significant differences between the two groups in muscle strength of the trunk. Grip strength and knee extension torque were significantly higher in the EH group (p = 0.043-0.046). Physical activity: In the EH group, physical activity time above 3 METs was significantly longer than the one in the NEH group (p = 0.024).
CONCLUSION: Our results suggested that past or present exercise habits could have some influence on muscular strength and people with sporting experiences would stay active even on a day without workout. However, we did not find a clear difference in body composition. This probably resulted from the fact that the EH group included those who discontinued exercise more than 10 years ago and those who started exercising within a year. Furthermore, a previous study also pointed out that child-raising might help increase muscle mass for women (2). We need to examine these factors in a future study.

LIFESTYLE AND HEALTH OF DIFFERENT ADULT AGE GROUPS

WILHELM, M.
UNIVERSITY OF PÉCS

INTRODUCTION: Life expectancy and health without limitations is depending on lifestyle factors as well. Among many possibilities regular physical activity proofed to be an important factor. In Hungary among adults sedentary behavior is more common than active lifestyle, and as a consequence the regression of health starts earlier as it is expected. In our study we measured healthy young sedentary adults physiological and fitness parameters and compared them to an active middle aged or elderly population.
METHODS: Subjects were assigned into 3 groups: Group 1 (G1) subjects age was in the range of 45-55 years (N= 43, mean age: 49.09±0.58y), in Group 2 (G2) from 55-65 years (N=22, age 59.20±0.82 y), Group 3 (G3) young inactive university students (N=16, 23.85±3.15y). In G1 and G2 all the volunteers were physically active, regularly participating in recreational activities and sports throughout their life, but none of them participated in elite sports. Most of their PAs mentioned were cycling, hiking or walking in town, jogging. Subjects in G3 were mostly inactive healthy young individuals. A six-minute walking test (6MWT) was conducted to measure aerobic capacity/endurance (Enright 2003). At the end the distance covered in meters, expected distance, maximal Heart Rate (HRmax) and O2-saturation with a pulseoxymeter (Spirodoc) was registered.
RESULTS: The results of the 6MWT in G1:583.5m, and G2:693m reached the expected distance calculated, while in the covered distance was 666.94±46m while the expected (894m) was much higher, although the body composition profile BMI was lower than in the older population. Their VO2max calculated according to Laskin et al.(2007) G1 41.87ml/kg/min, G2 42.18ml/kg/min, while in G3 37.05ml/kg/min. Intensity of the walk measured with the maximal HR were over 75% in each group tested, O2-saturation did not change significantly at the end of the walk.
CONCLUSION: Results collected with the 6MWT suggest that in the Hungarian population younger sedentary population seems to be in worse fitness and health status than the much older active population.

SPONTANEOUS LOCOMOTOR ACTIVITY REDUCES ANXIETY-LIKE BEHAVIOR IN ENVIRONMENTAL ENRICHMENT.

SUDO, M., ANDO, S.
PHYSICAL FITNESS RESEARCH

INTRODUCTION: EE involves housing conditions that facilitate enhanced sensory, cognitive and motor stimulation (1), which leads to reduction in anxiety-like behavior. The beneficial effects of EE on anxiety-like behavior is thought to be due to increases in locomotor activity. However, given that EE usually involves wheel running, it is still unclear whether reduction in anxiety-like behavior in EE is ascribed to increases in wheel running activity and/or locomotor activity in the absence of wheel running. Therefore, the purpose of the present study was to differentiate between effects of wheel running activity and locomotor activity on anxiety-like behavior in EE.
METHODS: The present EE consisted of running wheel, slope, tunnel, and small hut. Wistar rats were divided into four different housing groups (standard environment: SE; only running wheel group: EE-W; EE without running wheel (only slope, tunnel, and hut) group: EE-S; and EE, n=6, each). Locomotor activity of each rat was continuously recorded using a recently developed three-axis accelerometer that was embedded in the back. After exposure to each environment for 6 weeks, the animals were submitted to the light–dark exploration test to assess anxiety-like behavior. All experimental data were expressed as mean ± standard deviation. The level of significance was set at P<0.05.
RESULTS: The present EE consisted of running wheel, slope, tunnel, and small hut. Wistar rats were divided into four different housing groups (standard environment: SE; only running wheel group: EE-W; EE without running wheel (only slope, tunnel, and hut) group: EE-S; and EE, n=6, each). Locomotor activity of each rat was continuously recorded using a recently developed three-axis accelerometer that was embedded in the back. After exposure to each environment for 6 weeks, the animals were submitted to the light–dark exploration test to assess anxiety-like behavior. All experimental data were expressed as mean ± standard deviation. The level of significance was set at P<0.05.
CONCLUSION: Wheel running activity reduced anxiety-like behavior in the EE-W group. Locomotor activity reduced in the EE-S group as compared with other EE groups (EE-W and EE), suggesting that locomotor activity reduced in the absence of wheel running. Nevertheless, anxiety-like behavior reduced in the EE-S group. Hence, the present study suggests that both wheel running activity and locomotor activity in the absence of wheel running reduce anxiety-like behavior, but locomotor activity in the SE does not despite the same amount of locomotor activity.

THE NEW SIMPLE PHYSICAL ACTIVITY QUESTIONNAIRE IS USEFUL FOR ASSESSING PHYSICAL ACTIVITY OF JAPANESE

MUTSUMI, K., KUMIKO, M.
WAYO WOMENS UNIVERSITY

INTRODUCTION: It is known that appropriate eating habits, an active life style and getting enough rest are important for maintaining and promoting health. In the assessment of the subjects in the early stage of the Specific Health Checkups and Counseling (SHCC), it is necessary to determine their exercise and eating habits accurately and quickly for effective health education. In our previous research using a new simple physical activity questionnaire we developed, we showed a significant and positive correlation between the physical activity score (PA score) from the questionnaire and daily step counts (STEPs). However, further investigation is necessary to make the questionnaire more reliable. The purpose of this study was to investigate the validity of the questionnaire to assess physical activity of healthy Japanese.
METHODS: Physical activity amount was measured for one week using a triaxial accelerometer in 30 healthy Japanese males. Daily STEPs and metabolic equivalents (Mets) were calculated. Physical activity level without equipping the triaxial accelerometer was calculated as 1 Met. Prior to the measurements, the questionnaire composed 14 questions was conducted, and the PA score (up to 28 points) was calculated. The relationships between the PA score and Daily Steps, and Mets were assessed by Pearson's correlation coefficient.
RESULTS: PA score was distributed from 1 to 26 points (12.7 ± 5.7). STEPs was distributed from 4469 to 16956 steps (9545.6 ± 3129.4). Mets was distributed from 1.82 to 1.22 (1.43 ± 0.15) . There was a significant and positive correlation the PA score and Steps ($r= 0.59$, $p< 0.01$), and Mets ($r= 0.77$, $p< 0.01$).
CONCLUSION: The higher the PA score was, the higher the STEPs and Mets were, suggesting that our new simple physical activity questionnaire may be useful for assessing subject's physical activity in the SHCC.

QUALITY DIMENSIONS AND QUALITY RESEARCH IN HEALTH SPORT PROGRAMS

WITTELSBERGER, R., TIEMANN, M., BÖS, K.
KIT , SRH UNIVERSITY OF APPLIED HEALTH SCIENCES

Introduction
According to the "Ottawa Charter for Health Promotion" (WHO, 1986) "Health Sport programs" are defined as well structured exercise programs, adjusted to persons with sedentary behavior focusing on the promotion of health resources as well as health behavior and a supportive environment. To promote public health and improve health care, health insurances in Germany support the development, implementation and evaluation of specific health sport programs. High quality standard is needed to meet the funding requirements. Nevertheless, currently only few programs meet the required criteria concerning structure, process and outcome quality (Donabedian, 2005). Therefore, the aim of this study was to present different quality dimensions on the basis of the best practice health sport program called "AOKardio". This 10-week-program is proposed for persons who (re)start with physical activity. Structure and contents of this program follow the requirements of the prevention guideline of the health insurances in Germany as well as the FITT-recommendations (frequency, intensity, time, type of exercise) for health sports programs. The intervention takes place 1x/week for 90 minutes and is structured into 7-sequences.
Methods
For the structure quality the logic model was implemented as a tool for visualizing how the program will work (Mc Cawley, 1995). For the process quality two different questionnaires were applied (Tiemann et al., 2006; Henn et al., 2012). For the outcome quality a pre-post-test design with a control group (nutrition program) was conducted to measure different effects on health outcomes. Besides the aerobic endurance (2km walking-test) further parameters were assessed by questionnaires (BMI, physical fitness, subjective health status, body concept, mental health, Sport oriented self-efficacy).
Results
The results indicate an overall good or very good quality level of the "AOKardio-program". In structure and process quality levels of 92% and 79% were reached. In the outcome-analyses only aerobic endurance ($p\leq.001$; $df=60$; $t=4,67$) and BMI (BMI: $F= 28$; $p\leq.001$; $eta2=.114$) went statistically significant, but the last one – as expected – towards the CG (nutrition program).
Conclusion
The central goal to ensure a high quality of health sport programs was adapted in the example "AOKardio" through splitting and considering all three aspects of quality. Statistically significant effects were reached for endurance resp. aerobic capacity. Other parameters still changed positively, but without statistically significant results. This could be explained by the health oriented topic of the CG. In addition, training once a week may not be enough. Overall, there is an urgent need for long-term follow-up studies for different target groups.

EFFECTS OF DIFFERENT PEDALING CADENCES ON MOTOR-COGNITIVE DUAL-TASK PERFORMANCES AND CARDIO-RESPIRATORY RESPONSES

ISHIDA, K., SUGIMORI, H., ZHANG, L., KATAYAMA, K.
NAGOYA UNIVERSITY

INTRODUCTION: The motor-cognitive dual-task is thought to be effective in preventing dementia. It can induce deterioration of one or both task performances, which is called "dual-task interference". Little is known about the effects of changing the difficulty of motor-task on one or both task performances and, additionally, on cardio-respiratory responses during cycling. The purpose of this study was to elucidate the effects of changing pedaling cadence on each task performance and cardio-respiratory responses during dual-task.
METHODS: Twenty young participants pedaled on a cycle ergometer at their preferred cadences and 10 rpm faster or slower than preferred ones (more difficult task) as constant and precise as possible for 5 min each in a random order. Exercise intensity was adjusted to 40% of their heart rate reserve. The Trail Making Test-B (TMT) cognitive task was performed during rest (single cognitive task; CT), and in the last 3 min of each pedaling cadence simultaneously (dual-task; DT), preceded by single motor task (MT) for 2 min as reference. We measured minute ventilation (VE), breathing frequency (fb) and heart rate (HR) as cardio-respiratory responses, error rate and reaction time of TMT as cognitive performances, and average and coefficient of variation (CV) of cadences as motor performances.
RESULTS: VE, fb and HR during DT significantly increased within 10% as compared with those during MT. Those during CT were also significantly higher than those at rest. As for the motor performances, the CVs at DT were significantly higher than those at MT in all speeds.

The average cadences during DT in faster condition tended to decrease as compared with those during MT (71.3 vs 69.9 rpm, p=0.054) but there was no significant difference between DT and MT in all speeds. Error rates for the cognitive performances during DT showed significant increase as compared with CT (6.0%) under slower (8.0%) and faster (9.9%) conditions. Reaction times during DT also tended to increase under the faster condition (p=0.052) but no significant differences were found between DT in all speeds and CT.
CONCLUSION: As expected, cardio-respiratory responses during DT were additive of these during MT and CT. Our main findings are that the cadences during DT oscillated greater than those during MT, and the cognitive task during DT was more easily mistaken than that during CT. These results indicate the deterioration of both motor and cognitive performances during dual-task. Interestingly, the directions of changes in both task performances by DT in all speeds were different in each participant although they were similar within individual. This may because the strategy for DT interferences would be settled intra-individually regardless of difficulty of exercise.
It is concluded that both cognitive and motor task performances decrease during cycling especially under the faster cadences. Our results suggest the possibility for settled intra-individual strategy for dual-task interference regardless of cadences.

24RD ANNUAL ECSS CONGRESS PRAGUE/CZECH REBUBLIC, JULY 3-6. 2019 HEALTH BENEFITS OF A REGULAR PHYSICAL ACTIVITY PROGRAM IN UNIVERSITY STUDENTS GYEBROVSZKI ÁDÁM1, GARAI KITTI3, KVELL KRISZTIÁN3, ÁDÁM

GYEBROVSZKI, A.

PTE-TTK-BDI

INTRODUCTION: Nowadays noumerous data are avaiable about healty lifestyle and the effects of regular physical activity. University students mostly have information about the topic through the social media. The amount of information and their health condition and lifestyle do not correlate with each other. Their health status and physical conditions are regularly under the expectations. The aim of our study was to measure the impact of a regular long term physical activity program on previously inactive subjects, studying numerous physiological, psyhological and immunological parameters.
METHODS: Subjects were voluteer university students, participating in a six mounts long physical activity program at the university of Pécs, Hungary. 16 subject (23.85 ± 3.15 age, F N=14; M N=2) completed the full program. During the study 60 min long exercises were conducted, 3 times a week with settled time, average training time was 180 min/ week. Sessions included strength training (40 min, max 85% intensity) and cardiovascular/aerobic exercises (walking, jogging 20 min, max 65%) periodized. The study lasted 6 months with 3 measurements (initial data/T0, third month data/T1 and closing data/T2). Questionnaries were filled (SF-36, QOL), anthropometric parameters, cardio-respiratory measurements (heart rate/HR, blood-pressure/BP, O2-saturation), physical endurance with the 6 minute walking test (6MWT), and handgrip strength test were carried out. Blood and immunological parameters (sjTREC, cytokines) were also measured.
RESULTS: The majority of the analyzed parameters changed. BMI did not change, although body fat percentages decreased (T0: 30.07±6.3%, T1: 28,1±6,8%, T2: 29,51), we found significantly decreased skin-folds (e.g. Biceps T1 p= 0,001; T2 P=0,003, Triceps T1 p= 0,001,T2 P=0,002; Pectoralis: T1 p= 0,002, T2 P=0,032; Abdomen: T1 p= 0,001, T2 0,012; Suprailliacal: T1 p= 0,001, T2 0,001; Thigh T1 p= 0,01, T2 0,001). Muscle volume increased from 29.11±3.7% to 30.82±5.5% and 29.6% in average. Resting HR systolicBP were lower (6.94Hgmm), the diastolicBP also compared to T0. In the 6MWT (T0 666.94±46m), at T2 727.38m achievement was registered (T0-T2 p= 0.001), VO2max increased 3.36 ml/kg/min in average. Significantly decreased bloodsugar concentration (T0: 4.87, T1: 4.67, T2: 4.55 P=0.001) was measured. Insulin sensitivity (P=0.0007) and CK concentration significantly increased (P=0.0002). Decreasing CRP concentration was found (T0: 1.89, T1: 1.28, T2: 1.,16) .
CONCLUSION: Data at T1 and T2 show significant improvement, suggesting that regular physical activity is beneficial in terms of health and fitness in adulthood as well.

EFFECTS OF ACUTE EXERCISE WITH DIFFERENT PERCEIVED EXERTION ON CARDIOPULMONARY FITNESS AND ENJOYMENT IN SEDENTARY MEN

LEE, C.L.1, HSU, W.C.2, CHENG, C.F.3

1:NATIONAL SUN YAT-SEN UNIVERSITY 2:UNIVERSITY OF TAIPEI 3:NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: High-intensity interval exercise (HIIE) is a time-efficient exercise intervention that results in similar physiological adaptations as moderate-intensity continuous exercise (MICE) [1] and has higher enjoyment than MICE [2, 3]. However, the effects of acute reduced-exertion high-intensity interval exercise (REHIE), HIIE, and MICE on cardiopulmonary fitness and exercise-induced enjoyment response are not well understood [4]. The study aimed to examine the physiological and psychological responses to a single bout of HIIE, REHIE, and MICE in sedentary males.
METHODS: This study used a randomized and crossover design to test the effects of the HIIE, REHIE, and MICE on cardiopulmonary fitness and enjoyment responses in sixteen healthy sedentary males. In the familiarization trial, participants performed a graded exercise test for determining maximal power output (Wmax). During the following visits, participant undertook a single bout of HIIE (5×2-min sprint at 85%Wmax, a 2-min resting interval between sprints at 30%Wmax), a single bout of REHIE (2×1-min sprint at 90%Wmax, alternating with 10-min and 8-min resting interval at 50%Wmax following sprint), and a single bout of MICE (exercise at 65%Wmax for 20-min).
RESULTS: During the 20-min of exercise, oxygen consumption (VO2), carbohydrate/fat oxidation rate, and energy expenditure (EE) were not significantly different among conditions (P > .05). During the 60-min of post-exercise, VO2 and EE approached near significances between HIIE and MICE (P = .06), and the average heart rate (HR) was significantly higher in HIIE than that in MICE (108 ± 15 vs. 100 ± 14 bpm, P < .05), but the carbohydrate/fat oxidation rate was not different among all conditions (P > .05). The rating of perceived exertion (RPE) during 20-min of exercise in HIIE was significantly higher than those in REHIE and MICE (HIIE vs. REHIE vs. MICE: 18 ± 1 vs. 14 ± 2 vs. 16 ± 2, P < .01), and RPE in MICE was also significantly higher than that in REHIE (P < .01). The enjoyment during exercise was increased by ~42 – 54% in REHIE and MICE compared with HIIE, respectively (P < .01); the physical activity enjoyment scale (PACES) after exercise was increased by ~18% in response to REHIE and MICE versus HIIE (P < .05).
CONCLUSION: The RPE in REHIE was lower than those in HIIE and MICE during a single bout of exercise. During the recovery period, the higher HR, VO2, and EE in response to HIIE were approached versus MICE; however, HIIE did not differ from REHIE. Our findings suggest that REHIE can be a proper alternative to HIIE for the sedentary individual with no vigorous interval exercise experiences. DIALOGICAL PREVENTION OF SPORTSPERSONS FRUSTRATION

PLESTED-ALVAREZ, M., ACEVEDO-ZAPATA, J.

UNIVERSITY OF ANTIOQUIA

INTRODUCTION: A wide documentary research to determinate sport frustration was carried out.
In the sportspersons of high performance that affect the social, family, professional and physical dimensions of their self-concept. These may be related to injuries or poor results against high expectations for performance, making low adaptive stress and anxiety patterns causing a low capacity for tolerance of frustration (González, 2002).
Preventive pedagogical strategies to avoid the potential physical and psychological consequences of sport frustration by applying pedagogical communication between sportspersons, coach and the technical team to strengthen the communication processes and emotional way of inter and intrapersonal intelligence to prevent consequences of sport frustration in order to develop them greater resilience allows resolving the conflict or lock before or during a sporting activity.
METHODS: The terminology modeling, the diacronic-sincronic study of conceptual analysis in specialized contexts (Plested, 2010), the self-concept (Shavelson, et al., 1976), the frustration theory (Shorkey & Crocker, 1981) the emotional inteligence, resilience in high performance sport (Schinke et al, 2004, 2018) and the communication in education (Kaplún, 1998) are the theoretical-methodological basis with which this study was carried out.
Results and discussion: Sportspersons apparently have a very high self-concept of their abilities and about themselves. However, their life histories confirm that many of them suffer very strong frustrations when they don't get the expected results due to accidents before, during or after a competition, because that 'removed them from circulation'.
We concluded that the process of training requires a focus on the importance of pedagogical communication to ensure an excellent teaching and training. Regardless of which the stage of the competition is a clear communication between the sportsperson and the coach assures the best performance quality. This dialogic-pedagogical strategy coupled with the development of a better inter and intrapersonal emotional intelligence constitute a protective factor. This allows high-performance sportspersons gradually develop better resilience capacity to cope with any difficulties which may have impact on their self-concept and avoid negative effects on their well-being.

CHANGES IN HORMONE LEVELS WITH EXPOSURE TO STUDENT STRESS: THE CHESS PILOT STUDY

CRACK, L.A., DOYLE-BAKER, P.K., STOKES, R.E., LEBRUN, C.M.

HUMAN PERFORMANCE LAB, UNIVERSITY OF CALGARY, CALGARY AB.; DEPARTMENT OF FAMILY MEDICINE, UNIVERSITY OF ALBERTA, EDM., AB., CANADA.

INTRODUCTION: Recent literature highlights elevated stress levels and changes in overall mental health have reached an alarming prevalence among post-secondary students. This is especially true among female students when compared to their male counterparts. (1) Salivary cortisol levels are often employed as a measure of the physiological stress response in humans. The cortisol awakening response (CAR) is the increase during the first 30 minutes of waking, whereas the diurnal cortisol measure is the slope of the trend line associated with the periodic samples throughout the day; excluding the CAR (2). While acute stress causes an increase in cortisol, chronic stress has conflicting associations with both hyper- and hypocortisolism (3), and mixed evidence exists regarding the effect of burnout on CAR (4). The primary aim of this study was to determine the impact of chronic life-stress as measured by the Student-Life Stress Inventory (SSI) (5) on CAR among female undergraduate students, while controlling for menstrual cycle phase.
METHODS: Eighteen full-time undergraduate students are enrolled. Half of the participants are on hormonal contraceptives and when compared to those not on birth control, the contraceptives users are slightly older (mean age, standard deviation (SD); 22.2 SD 2.2 versus 20.1 SD 0.8 years). Participants self-reported the dates of their first menstruation day and day 21 of each cycle was calculated as a proxy measure for the mid-luteal phase. A diurnal cortisol profile was determined through salivary samples, collected on day 21 at 4-time intervals (30 minutes after waking, noon, evening and night-time).
RESULTS: Seventeen participants have completed one or more sets (3) of salivary samples for a total of 33 analyzed profiles. No significant difference was found for CAR within groups ($p = 0.58$) or between groups ($p = 0.37$). Thirteen (76%) of the participants displayed sub-normal CAR during at least 1 sample collection, while 47% (8) of the participants had sub-normal CAR over all collection dates (mean 9.2 SD 2.2 nmol; range 6.9-13 nmol) when compared to the normal range (14-25 nmol). Six participants (with 2-3 sample sets over 12 weeks) have values crossing time periods associated with acute stress (final exams) and displayed a significant change in SSI score ($p = 0.04$) despite consistently low CAR.
CONCLUSION: This pilot data shows a blunted CAR during exposure to acute changes in stress associated with the academic schedule. Given existing contradictory evidence regarding the effect of chronic stress on CAR and reports that CAR is not dependent on sleep quality in females (6), further research is warranted to explore this unreported trend in the female student population.

COMPARISON OF WELL-BEING DIFFERENCES IN ELDERLY PEOPLE WHO RECEIVE PENSIONS WITH ELDERLY PEOPLE WHO LIVING WITH ACCUMULATED MONEY IN SAMUT SONGKHRAM PROVINCE THAILAND

BUNGMARK, W., NEELAPAIJIT, N.

SILPAKORN UNIVERSITY

Background: Thailand is going to enter the aging society. From the population of Samut Songkhram province has entered the aging society already. The researcher team is interested about source of income will affect well-being in Thai elderly. In Thailand elderly people are mostly able to divide the source of income into 2 types. The first type is the government worker when retired will receive a pension and another type is those who work for the private sector or do personal business these people have to use accumulated money to live on retirement. If we know the impact of different sources of income to well-being. We can development model physical activities with creative Thai way of life suitable for elderly who had different source of income to promote their well-being. To prepare Thailand to enter the aging society in the future.
Objective: Comparison of well-being differences in elderly people who receive pensions with elderly people who living with accumulated money. In order to properly organize physical activities with creative Thai way of life to promote well-being for Thai elderly.
Method: The research method was survey research, a multi-stage random sampling was used in this study. There were 60 subjects. Frist group of 30 subjects were elderly people who receive pensions and second group of 30 subjects were elderly people who living with accumulated money. The data were collected by using questionnaire about status of well-being. Divided into 4 areas included physical wellness, psychological wellness, social wellness and spiritual wellness. The data were analyzed by using average, standard deviation, independent t-test. The statistically significant at .05.
Results: Elderly people who receive pensions had physical wellness (=4.01, S.D. 0.48),
psychological wellness (=4.26, S.D. 0.53), social wellness (=3.87, S.D. 0.62), spiritual wellness (=4.49, S.D. 0.48), and total wellness (=4.16, S.D. 0.45) different with elderly people who living with accumulated money had physical wellness (=3.59, S.D. 0.43),
psychological wellness (=3.78, S.D. 0.41), social wellness (=3.45, S.D. 0.59), spiritual wellness (=3.77, S.D. 0.41), and total wellness (=3.65, S.D. 0.33) with statistical significance at .05.
Conclusion: Elderly people who receive pensions had physical wellness, psychological wellness, social wellness, spiritual wellness, and total wellness better than elderly people who living with accumulated money. From the difference of sources of income refer to elderly people who receive pensions interested in physical activities with creative Thai way of life to promote spiritual wellness. But elderly people who living with accumulated money interested in physical activities with creative Thai way of life that causes extra income.
Key words: well-being, elderly, aging society, Thai way of life

TRAINEES PERCEPTION TOWARDS TRAINING METHODS IN THE NIGERIAN PRIVATE UNIVERSITY SYSTEM

OLAOSEBIKAN, T.

JOSEPH AYO BABALOLA UNIVERSITY

ECSS Congress Prague, July 3-6 2019
Training and Testing-Trainees Perception towards Training methods in the Nigerian Private University system
Olaosebikan, T.
Joseph Ayo Babalola University
Introduction
Training for trainees is to enhance physical and mental productivity and overall performance of the training system. This is due to the recognition of the important role of training in attainment of good health.
Methods
Consequently, this study investigated the perception of trainees towards training methods in the Nigerian Private University system, using Joseph Ayo Babalola University, Ikeji-Arakeji, Osun State as a case study. Collection of data for the study was effected through the use of questionnaire with a sample size of 263 drawn by stratified random sampling. The data was analyzed using descriptive and inferential statistics.
Results and discussion
The findings of the study show that the perception of 73.88% of the respondents towards training methods is pointed towards enhancement of their efficiency, productivity and personal fitness. The study recommends that management of private Universities in Nigerian must ensure that appropriate training for their trainees form the heart of their cardinal mission.

MODERN COACHING

RAHMANI, M.

ISLAMIC AZAD UNIVERSITY

Coaching is a part of the process to performance. Coaching is developed into a profession. In English language a coach is a vehicle mainly used for long distances. Long distance is a remarkable aspect, best coaching can be done in long term projects. Using this English version of coach figurative, than an analyse is, that a coach is transporting someone from one point to another point. Philosopher Socrates was a coach: helping people to understand, but as a coach one cannot take care for the understanding. Another definition is improve of learning possibilities and performances of others. In history of sport coaching one can see that the definition transporting someone from one point to another was done almost literally. The coach was deciding, athletes had to follow without personal contribution. There are still coaches, countries and cultures which are using a dictatorial style of coaching. Dictatorial coaching is developing into

a modern form; coaching leads to self-management. Coaching was developing, mainly the personal style of the coach was modifying. A modern style of coaching is helping to develop a sportsmen/women into self-management in order to perform by observing, listening, facilitating and advising (Visser NIFISA Kanoya). Another definition is: helping others in their development and growth. (Landsberg USA) Landsberg developed the GROW model. Several types of coaches: authoritarian, democratic, liberal, intensive and functional; many are combination types (Janboers NL). Competences of good coaches: analytic, autonomus, organized, closed character, complete, powerfull, independent, original, system driven, theoratical, resolute and visionair. (Myers, Briggs, Murphy Canada). Coach duty: scouting, training and coaching the matches. The coach trains and coaches the match. Differences between training and match: training is learn and practice, average pressure, sub-maximum performance, reproducible, variable and many forms. Match is: apply and perform, high pressure, maximum achievement, non-reproducible, and fixed. The gap between training and match can be a wide one. The coach has a bridge function between training and match. A coach possess following competences: high-quality sport specific and sport technical skills; methodical and didactical skills; influential competences; task adequate social skills; good ability to express orally and in writing; excellent general education; diplomatic and representative skills. A coach has to develop true sportsmanship, fair play (NOC Canada Coaching: listen first, think and finally do; keen observation and analysis; accuracy, giving attention; meeting up to appointments, initiative. A coach has knowledge about the sport specific techniques, physiology, psychology. Conclusion: Modern coaching is indispensable for performance. Coaching needs scientific approach. For benefit of athletes and the development of sport the gap between science and active field of sport has to be closed.

EFFECT OF PARTICIPATION IN SPORTS TEAM DURING OVERSEAS STUDY PROGRAM ON NON-NATIVE LANGUAGE PROFICIENCY

MIYAMOTO, H., WATANABE, K.

CHUKYO UNIVERSITY

Introduction

Sports and communication go hand in hand. Not only does interpersonal communication promote team success, but sports also offer a setting to improve communication efficacy (Ishak, 2017). Moreover, a recent study revealed that learning a foreign vocabulary while performing a concurrent physical activity is more effective than learning the same vocabulary while inactive (Liu, Sulpizio, Kornpetpanee, & Job, 2017). However, most research has concentrated on memory such as memorizing vocabulary. This study aimed to investigate the effect of participation in physical activity such as belonging to sports teams during an overseas study program on not only memorizing vocabulary but also improving the 4 language skills: reading, listening, speaking, and writing.

Methods

Twenty-five international students including 12 athletes (Group 1) and 13 non-athletes (Group 2) attending a university in the United States were enrolled in this study. They were asked questions to ascertain the following information: their nationality, first language, length of stay in the United States, language they use at the university, the amount of study in English per day, sport they participate in at the university (only for Group 1), and level of English understanding in classes (both before and after enrolling at the university in the United States). The question to assess the level of English understanding in classes focused on the 4 language skills: reading, listening, speaking, and writing. The levels of understanding were compared between Groups 1 and 2 before (Pre) and after (Post) their overseas study program in the United States by the Man-Whitney test and Wilcoxon Signed rank test using SPSS.

Results

The levels of understanding regarding all four skills in Group 2 were significantly higher than those in Group 1 at Pre ($p < 0.05$), but not at Post ($p > 0.05$). There were significant increases in the levels of understanding regarding all four skills from Pre to Post only in Group 1 ($p < 0.05$).

Discussion

Despite the difference in the baseline, this study revealed differences in development patterns in the level of understanding regarding reading, listening, speaking, and writing English between students who do and do not participate in sports. These results suggest that participation in physical activity such as belonging to a sports team could be more effective for learning a non-native language during an overseas study program.

PST: COACHES AND SPORT PSYCHOLOGISTS: WORKING TOGETHER

JAENES SÁNCHEZ, J.C., CASADO-ALDA, A.

PABLO DE OLAVIDE UNIVERSITY , ISABEL I UNIVERSITY*

Psychological Skill Training PST (Weinberg & Gould, 2011) is an important field of expertise, and necessary to learn as part of coach education programs, due to the fact that coaches (C) spend more time with athletes and players than Sport Psychologists (SP). According to the experience at the Andalusian Center of Sport Medicine (CAMD), PST has to be an important part of the indirect intervention between SP and C to make athletes achieve his/her goals. Several authors emphasized the importance of PST in football; rowing ; sports in general, but specially in marathon (Jaenes y Caracuel, 2016), establishing the importance of interactions and Sports Classification according to some variables: surface, objects players use when they are training, the presence of teammates and opponents; but a new approach based on the idea of the interaction between coaches and players and their needs is necessary. Using a new schema based on Physical Training concepts as well as PST, will make athletes perform much better.

In this paper, the authors will present an example of PST for marathon runners, where C can share technical information, and SP works in their field of expertise to be more useful for their athletes. The advantage: PST is a practice coaches can assume without intruding on the SP.

Method

Participants

Ten C of Rowing, Canoeing and Track and Field were training at CAMD in 10 sessions based on PST structure.

Instruments

A worksheet with general PST instructions, and a notebook with worksheets that coaches filled out at home with physical training variables, and reviewed in the next session until the last group session. SP will added psychological variables to enhance different skills.

Procedure
Coaches applied the PST strategies according to the Psychological Skills they considered appropriate for different boats, specialties, and distances they run. Competitors had to apply these strategies at home, when they needed them in certain specific situations, and occurrences of negative thoughts or technical mistakes that they normally committed.
Results
This paper has been part of an indirect intervention at CAMD more than an experiment, but at the end of the intervention an Ad Hoc questionnaire was delivered, scoring in a Lickert Scale between 0 (nothing) and 5 (Absolutely agree) in four questions about satisfaction with the process and PST efficacy.
General Satisfaction with the Educational phase: Mean: 4.6; SD: 0,90; Program utility: Mean: 4.4; SD: 0,95; Coaches are able to apply: 4,1; SD: 1,01; Athletes consider PST useful: 4,2; SD: 0,93
Conclussions
According to Scientific literature and coaches interventions, PST is useful for coaches and athletes in different sports, and should be part of coach education in Federation programs and Seminars. These methods, also demonstrate its efficacy as part of coach and SP interactions.

EFFECT OF RUMINATION ON MENTAL HEALTH OF JAPANESE UNIVERSITY ATHLETES

NAKAMURA, M.1, KAWATA, Y.1,2, YAMAGUCHI, S.1,3, HIROSAWA, M.1,2, SHIBATA, N.1,2,3
1: GRADUATE SCHOOL OF JUNTENDO UNIVERSITY, 2: JUNTENDO UNIVERSITY, 3: JUNTENDO UNIVERSITY

Introduction
Rumination in the context of depression is defined as repetitive and passive thinking about one's symptoms of depression and the possible causes of these symptoms (Nolen-Hoeksema, 2004) . Rumination is known to affect mental health, but its specific effects on the mental health of athletes are unclear. Therefore, this study aimed to examine the effects of rumination on the mental health of Japanese university athletes.
Method
The participants were 821 Japanese university athletes (559 men, 262 women, *M* age = 20.0 years, SD = 1.24 years). We used Ruminative Responses Scale (RRS; Hasegawa, 2013) to assess rumination, and the General Health Questionnaire-30 (GHQ-30; Goldberg et al., 1979) to assess mental health. First, we confirmed the confounding factors. Next, to examine the effects of rumination on mental health, we carried out a logistic regression analysis by setting rumination (brooding and reflection scores) as the independent variables, mental health (GHQ-30 total score) as the dependent variable, and demographic data (sex and age) as covariates.
Results
Sex and age were extracted as the confounding factors. The regression analysis showed that "brooding" had a significant effect on GHQ-30; the high-brooding group had 4.9 times higher risk of poor mental health than did the low-brooding group (OR = 4.86, 95% CI = 3.00 – 7.85, $p < .001$). Similarly, "reflection" had a significant effect on GHQ-30; the high-reflection group had 2.9 times higher risk of poor mental health than did the low-reflection group (OR = 2.90, 95% CI = 1.75 – 4.80, $p < .001$).
Discussion
These findings revealed that rumination affects the mental health of athletes. Brooding involves constant negatively comparison of one's current situation to an unachieved standard, and it increased the risk for poor mental health by 5 times. Reflection in this context involves purposefully turning inward to evaluate one's depressive symptoms, and it is associated with a lower risk of poor mental health, compared to brooding.
Conclusion
Rumination affect mental health in athletes. Those with frequent brooding had 4.9 times higher risk of poor mental health, compared with athletes who did not tend to brooding. Similarly, athletes with frequent reflection had 2.9 times higher risk of poor mental health, compared with athletes who did not tend to engage in reflection.

RELATIONSHIP BETWEEN DEVOTION TO OTHERS AND LONG-TERM YIPS SYMPTOMS AMONG JAPANESE BASEBALL PLAYERS

NOGURI, R.1, KAWATA, Y.1,2, YAMAGUCHI, S.1,3, SHIBATA, N.1,2,3, HIROSAWA, M.1,2
1: GRADUATE SCHOOL OF JUNTENDO UNIVERSITY, 2: JUNTENDO UNIVERSITY, 3: JUNTENDO UNIVERSITY.

Introduction
Yips symptoms worsen pitching performance among baseball players. Some baseball players have retired due to yips onset. Long-term yips symptoms are not only a hindrance for regular players, but also a crisis in their competitive life. Specifically, physical symptoms (e.g., sense of wrist being locked) and psychological symptoms (e.g., negative thinking) have been reported. However, few researchers have examined the psychological characteristics of baseball players with prolonged yips symptoms. Clarifying this is useful for secondary prevention, early treatment, and intervention. Therefore, we aimed to examine the psychological characteristics of baseball players with prolonged yips symptoms.
Methods
Participants were 110 male baseball players (41 pitchers, 8 catchers, 29 infielders, and 32 outfielders, average age = 21.4 years) who had over 10 years of experience in baseball. Participants completed the Depression Related Personality Trait Scale ("perfection in work" and "devotion to others") and reported the duration of their yips symptoms. We divided participants into 3 groups based on the duration of their yips symptoms: non-yips group, short-term yips group, and long-term yips group. Specifically, we used selection criteria by referring to previous studies. Participants who experienced over 3 months of yips symptoms comprised the yips group, and then we classified

short-term and long-term yips groups based on the median value of symptom duration within the yips group. We compared median values of perfectionism in the task and devotion to others in each group using the Kruskal-Wallis test.
Results & Discussion
The non-yips group included 97 players; the short-term yips group included 6 players (average symptom duration = 8.8 months); and the long-term yips group had 7 players (average symptom duration = 50.3 months). Results showed that the long-term yips group showed significantly higher scores on devotion to others than did the non-yips and short-term yips groups. This result was aligned with our previous study wherein players with yips symptoms (not considering symptom duration) had higher devotion to others than the players without yips symptoms (Matsuzaki et al., 2017). Based on these findings, we concluded that the high devotion to others may be related to prolonged yips symptoms. Devotion to others is one of the psychological characteristics of baseball players with prolonged yips symptoms.

INFLUENCE OF SOCIAL SUPPORT ON EMOTIONAL REGULATION AMONG JAPANESE UNIVERSITY ATHLETES

MAKI, Y.1, KAWATA, Y.1,2, YAMAGUCHI, S.1,3, HIROSAWA, M.1,2, SHIBATA, N.1,2,3
1: GRADUATE SCHOOL OF JUNTENDO UNIVERSITY, 2: JUNTENDO UNIVERSITY, 3: JUNTENDO UNIVERSITY

Introduction
In sports, Emotion control is important for stable and appropriate functioning (Lane, 2012). According to the process model of emotion regulation, two strategies "Reappraisal" and "Suppression" are suggested (Gross, 1998). Reappraisal is defined as the strategy of cognitive change that involves construing a potentially emotion-eliciting situation in a way that changes its emotional impact. Suppression is defined as the strategy of response modulation that involves inhibiting an ongoing emotion-expressive behavior. Good social relationships are important for emotion regulation (Gross & John, 2003), and "social support" can be cited as underlying social relationships. Social support is psychological or substantive aid obtained from various people around himself (Hisada, 1987). However, the relationship between emotion regulation and Social support has been still unclear. Therefore, this study aimed to examine the influence of social support on emotion regulation among Japanese university athletes.
Methods
Data were collected from 821 Japanese university athletes (559 male and 262 female athletes; Mage = 20.0 years, SD = 1.24 years). We collected data including demographics, Emotion Regulation Scale (Gross & John, 2003), and Multidimensional Scale of Perceived Social Support (Zimet & Gregory et al., 1998). First, we divided participants into 2 groups based on median values of social support score: high and low social support groups. We calculated descriptive statistics to confirm confounding factors. Next, we performed logistic regression analysis setting sex differences, grade levels, and roles in teams as confounding factors.
Results and discussion
Results showed that the high social support group used reappraisal strategy 2.99 times higher than did the low social support group (OR = 2.99; 95%CI; 2.21–4.03; $p < 0.01$). "Thus, social support from surroundings is presumed to promote the athletes' view things and thought processes. However, no significant difference was found in suppression strategy. Athletes often need to suppress their extremely emotions to achieve high performances or to not express their emotion to their opponent as a sports strategy. Therefore, social support may not be associated with suppression strategy.
Conclusion
Athletes receiving high social support used reappraisal strategy approximately three times more frequently than did those receiving low social support.

LOCAL AND REMOTE ISCHEMIC PRECONDITIONING IMPROVES SPRINT INTERVAL EXERCISE PERFORMANCE IN TEAM SPORT ATHLETES

CHENG, C.F.1, KUO, Y.H.2, CHIANG, Y.H.1, LIN, Y.S.2, LEE, C.L.3
1: NATIONAL TAIWAN NORMAL UNIVERSITY, 2: NATIONAL TAIWAN NORMAL UNIVERSITY, 3: NATIONAL SUN YAT-SEN UNIVERSITY

INTRODUCTION: The local (LIPC) and remote (RIPC) ischemic preconditioning, involves brief cycles of ischemia and reperfusion, might improve subsequent maximal oxygen uptake (VO2max) and endurance performance [2-4]. Recently, the sprint and high-intensity interval training are popular interventions to improve aerobic capacity and performance in untrained and trained individuals [1]. The aim of this study was to examine the effects of LIPC and RIPC on sprint interval exercise (SIE) performance in athletes.
METHODS: Fifteen male collegiate basketball players were recruited in this study. After a familiarization trial, participants performed an incremental cycling test and two control (CON) trials. During the following visits, participants performed LIPC, RIPC, or SHAM trial in a randomized crossover design, separated by at least 3 days, before conducting 6 sets of 30-s Wingate-based SIE. The peak (PPO) and mean (MPO) power output, total work, and percentage decrement score during SIE were analyzed. The heart rate and oxygen uptake were continuously measured during SIE. Blood samples for pH and lactate (La) concentrations were drawn before and after treatment, and 5-min after SIE.

RESULTS: The PPO (ICC = 0.93−0.98) and MPO (ICC = 0.77−0.91) power outputs at each sprint have good to excellent test-retest reliabilities. The total work during SIE in LIPC and RIPC were significantly higher than that in CON (LIPC vs. RIPC vs. SHAM vs. CON, 108.3 ± 8.9 vs. 108.4 ± 6.9 vs. 107.1 ± 8.6 vs. 106.0 ± 8.6 kJ, $P < 0.05$). The MPO at 3rd and 4th sprint in LIPC (+4.5%) and RIPC (+4.9%) were significantly higher than those in CON ($P < 0.05$). The percentage decrement scores of MPO in LIPC and RIPC were significantly lower than that in CON ($P < 0.05$). No significant interaction effect in PPO was found, however, the percentage decrement score of PPO in LIPC was significantly lower than that in CON ($P < 0.05$). No significant interaction effects in pH and La levels were found. Moreover, there were no significant differences in the accumulated exercise time at ≥ 80%, 90%, and 100%VO2max during SIE.
CONCLUSION: The potential mechanisms of ischemic preconditioning (IPC) for improving exercise performance might associate with attenuated ATP depletion, improved PCr resynthesis, increases in vasodilation and oxygen delivery and extraction [2-4]. This study found that both LIPC and RIPC could improve metabolic efficiency and SIE performance. Strength and conditioning professionals are encouraged to use the IPC for enhancing training quality during sprint interval training. Supported by grants from Ministry of Science and Technology, Taiwan (MOST 106-2628-H-003-008-MY2).

PHYSIOLOGICAL DEMANDS OF EPÉE FENCING PERFORMANCE

OATES, L., CAMPBELL, I., PRICE, M., MUNIZ-PUMARES, D., IGLESIAS, X., BOTTOMS, L.
UNIVERSITY OF HERTFORDSHIRE

INTRODUCTION: Understanding the demands of specific sports is becoming an important aspect for coaches and athletes. However, there is little research assessing the demands of the Olympic sport of fencing. International epée fencing competitions last between 9-11 hours (Roi & Bianchedi, 2008), and comprise of Poule fights (3-minute first to 5 points) which seeds knockout Direct Elimination (DE) fights (3X3 minute first to 15 points). There is limited research assessing the physiological demands of epée fencing performance during competition with the majority of studies simulating fights in a laboratory setting (Bottoms et al., 2011; and Bottoms et al., 2013).
The aims of this study were: to determine the physiological demands of epée fencing performance during competition and compare how the physiological demands change during different phases of the competition from Poule to DE. Furthermore, the movement demands during epée fencing competition would be ascertained using a tri-axial accelerometer based system.
METHODS: Eight male well-trained epée fencers competed in a competition consisting of 7 Poule and 7 DE fights. Core temperature via ingestible pill (TC), heart rate (HR), movement patterns, training load, and differentiated ratings of perceived exertion (RPE) were collected for all Poule and DE fights. Expired gas, and energy expenditure (EE) were measured using breath-by-breath gas analysis during selected fights. Capillary blood lactate concentration was collected post Poule 1 and 7, and post DE 1, 3, 5 and 7.
RESULTS: Maximal HR and RPE were greater in DE than Poule fights ($p<0.001$). There was a tendency for greater increases in TC in DE compared to Poule fights ($p=0.052$). Blood lactate concentration decreased ($p<0.001$) during the competition with Poule 1 blood lactate concentration being greater than Poule 7, DE 5 and DE 7. High oxygen consumption (~50 ml.kg-1.min-1) and EE (~13 kcal.min-1) were recorded in both Poule and DE. Fencers covered 3 times more distance in DE than Poule fights ($p<0.001$), however there was no significant between Poule and DE for distance covered per minute ($p=0.066$). High training load scores were also recorded with a significantly greater ($p=0.001$) training load per minute recorded during DE compared to Poule fights.
CONCLUSION: This is the first study to show an increased physiological strain, with high aerobic and anaerobic demands, as fencing competition progressed from Poule to DE. There is a suggestion of increasing reliance on alactic and aerobic energy systems as a competition progresses due to decreasing blood lactate concentration from Poule 1 to DE 7. Additionally, there was a considerable energy demand exhibited during epée competition stressing the importance of adequate fuelling to maintain performance.

EFFECTS OF MILD DEHYDRATION ON ARCHERY PERFORMANCE

APHAMIS, G., SAVVIDES, A., STAVRINOU, P.S., GIANNAKI, C.D.
UNIVERSITY OF NICOSIA

INTRODUCTION: Archery is a static sport with particularities of strength in the shoulder muscles (Ertan et al., 2003), but with great demands on cognitive function, as archers constantly focus on the target and arrow (Seo et al., 2012). Interestingly, cognitive performance can be negatively affected even by mild dehydration (Wittbrodt & Millard-Stafford, 2018). The aim of the present study was to investigate whether mild dehydration may have any effects on archery performance.
METHODS: 10 national level archers (men n=7, women n=3; age 18-25 y, height 171 ± 9 cm, body mass 74.4 ± 11.9 kg) volunteered for this study. Participants visited the archery area on two occasions, 7 days apart, performing 12 rounds of 6 arrow throws (similarly to archery competitions), once under eyhydration (EUH) and once under a dehydrated state (DEH) (24-h reduced fluid intake). Archery performance (points score) was calculated according to official archery regulations. Prior to each trial, urine specific gravity (USG) was measured to verify hydration status (dehydration cut off value 1.020) and a subjective feelings questionnaire related to thirst, fatigue and concentration was completed by the participants (10-cm visual analog scale, Shirrefs et al., 2004). Heart rate was continuously monitored during trials. Comparisons between trials were performed using Repeated Measures ANOVA, and statistical significance was set at $p < 0.050$.
RESULTS: At baseline, USG was 1.015 ± 0.004 and 1.032 ± 0.005 at EUH and DEH trials respectively ($p < 0.001$). At DEH baseline, the participants felt thirstier ($p < 0.001$) and less able to concentrate ($p = 0.016$). However, archery performance was similar between trials (EUH 550 ± 63 points, DEH 562 ± 59 points; $p = 0.155$). Heart rate was elevated during DEH compared with EUH, both at rest-baseline (DEH 84 ± 7 bpm vs EUH 77 ± 7 bpm; $p = 0.002$) and during the exercise phase (average HR: DEH 130 ± 14 bpm, EUH 121 ± 9 bpm, $p = 0.025$).
CONCLUSION: Mild dehydration did not impair archery performance over 72 arrow throws, despite the fact that the archers felt less able to concentrate when dehydrated. However, the elevated heart rate observed during the DEH trial indicates that there was a greater strain on the athletes. It is unknown whether in typical archery competitions, with higher amount of arrow throws (130-140), dehydration can have an adverse effect on performance.

DIFFERENCES IN THE SYSTEMIC REDOX INDEX AFTER EXPOSURE TO PARTICULATE MATTER AND OZONE IN STREET RUNNERS

VAISBERG, M., BACHI, A.L.L., FOSTER, R., LUNA, L.A., SA, M.C., KATEKARU, C.M., PAGANI, L.G., AMARAL, J.B., ROSSI, M., BARROS, M.P., VIEIRA, R.P., SANTOS, J.M.B.

FEDERAL UNIVERSITY OF SAO PAULO

INTRODUCTION: Regular practice of physical exercise in outdoor environment can expose the practitioners to high levels of pollutants in the air. In Sao Paulo (Brazil), during the winter the concentration of particulate matter (PM) raise due low incidence of precipitation, whereas during the summer there is an increase in the frequency of precipitation that reduce the PM concentration. However, the O3 concentration raise due the higher incidence of suns radiation. Pollutants inhalation can lead to an imbalance in the redox index. It is widely accepted that the regular practice of physical exercise improves antioxidant capacity. So, we aimed to investigate the PM and O3 exposure impact in the redox index of street runners.
METHODS: Blood samples from 14 recreational runners (11 male and 3 female, age=35.9+/-9.8 years, body fat=23.18+/-4.9%, maximal oxygen uptake=44.06+/-5.8 ml.kg-1.min-1) that live and training in the Sao Paulo city, were collected after 10 weeks of winter and summer seasons. It was analysed the plasma concentration of glutathione (GSH), oxidized glutathione (GSSG), trolox equivalent antioxidant capacity (TEAC), nitric oxide (NO), and thiobarbituric acid reactive substances (TBARS) by colorimetric method.
RESULTS: Lower GSH (winter=48.9+/-6.1, summer=44.7+/-4.9; p=0.043) and higher GSSH (winter=33.6+/-3.1, summer=36.4+/-2.8; p=0.002) concentrations were found in summer compared to winter values. NO, TEAC and TBARS levels was similar between the seasons (p values: 0.72, 0.95, and 0.51 respectively). Positive correlation was observed between NO and TBARS (p=0.01, Rô=0.67), and TEAC and TBARS (p=0.04, Rô=0.76), in winter season. In addition, positive correlation between NO and TBARS (p<0.001, Rô=0.83) was also observed in summer season. The redox power was higher during winter (winter=0.42+/-0.03, summer=0.38+/-0.03; p=0.002) compared to summer.
CONCLUSION: Higher O3 exposure lead to an imbalance in the redox index observed, not only, by the reduction of redox power due to high demand of GSH oxidation observed by the increase of GSSG levels, but also to the absence of correlation between TEAC and TBARS, and elevation of correlation value between NO and TBARS. This effect of O3 exposure can be attributed to the fact that it is a gas, which can penetrate the bloodstream easily impairing the oxidative status, while PM are partially filtered by the airway reducing it absorption and consequently attenuating its effect.

RELATIONSHIP BETWEEN IRON INTAKE AND HEMOGLOBIN MASS IN ADOLESCENTS TRAINED IN RESISTANCE SPORTS AND UNTRAINED, RESIDENTS IN INTERMEDIATE ALTITUDE

QUINTERO BARRANTES, K., VARGAS ZARATE, M., MORA PLAZAS, M., MANCERA SOTO, E.

UNIVERSIDAD NACIONAL DE COLOMBIA

INTRODUCTION: Iron is an important mineral for the body functions because it participates in the oxygen transport being part of the molecule of hemoglobin (Hb), a key protein in the uptake of this element by body tissues. The aim of the research is to determine the relationship between iron intake and hemoglobin mass, in a group of adolescents trained in resistance sports and another group of untrained, residents in the city of Bogotá D.C.
METHODS: This cross-sectional, analytical and correlational study involving 25 adolescents trained in resistance sports and 20 untrained adolescents. The iron intake (total, heme and nonheme) with its absorption enhancing (protein and vitamin C) and inhibiting factors (fiber and calcium) were measured by the 24-hour dietary recalls (5 step multiple – pass approach) and the food frequency questionnaire. The hemoglobin mass was measured according to the carbon monoxide (CO) rebreathing methodology described by Schmidt and Plummer (1).
RESULTS: In trained adolescents, the average hemoglobin mass was 12.52 g/kg ± 1.85 and in the untrained group of 11.16 g/kg ± 1.81. In both groups, the median hemoglobin mass of men was higher than that of women, this difference in both groups and by sex was statistically significant (trained p = 0.009, untrained p = 0.002). When comparing the medians of the groups in terms of total iron intake, no statistically significant differences were found between the groups and by sex (trained p= 0.07 and untrained p=0.17).
In the group of trained and untrained men there was a positive association between the total iron intake and the hemoglobin mass. In the trained group, this association was a moderate and positive correlation (r = 0.7, p = 0.01) whereas in the untrained group there was a strong association and considerable positive correlation (r = 0.85, p = 0.007). No correlation was found between total iron intake and hemoglobin mass in women (trained r = -0.2, p = 0.4 and untrained r = 0.05, p = 0.8).
CONCLUSION: In conclusion, the iron intake is associated with the increase in the hemoglobin mass, but this response is different according to sex, in adolescent men can be produced by the physiological changes of this stage (e.g. the increase in the rate of erythropoiesis) and therefore higher production of the hemoglobin mass.
Keywords: Iron Intake, Adolescent, Altitude, Hemoglobin mass.

IN WHICH PHASE OF SQUAT EXERCISES CAN ACTIVATE THE ABDOMINAL CORE MUSCLES MORE? DESCENDING, STATIC, OR ASCENDING PHASE?

GUNDUZ, S., CALIK, M., CIGERCIOGLU, N.B., ERDEM, M.M., DEMIREL, G.N., HARPUT, G.

HACETTEPE UNIVERSITY

INTRODUCTION: Squat exercises are commonly used as a functional exercise to strengthening lower extremity muscles (1). Squatting with abdominal core activation (ACA) was shown to increase lower extremity muscle activation (2). However, it is unclear if ACA level would

differ according to the squatting phases. Thus, the purpose of the present study was to investigate whether enhanced abdominal core activation (ECA) levels would differ during different phases of squat exercises.
METHODS: Eleven healthy individuals (Age: 24.6±1.9 years; BMI: 22.7±2.9 kg/m2) were included in this study. Surface electromyography (EMG) was used to measure bilateral internal oblique/transversus abdominis (IO/TA) muscle activation levels during two-leg (WLWS) and dominant leg wall-squat (DLWS) exercises at 60 degrees of knee flexion. The exercises were divided into 3 phases (descending, static and ascending) by using synchronized video camera. The speed of the squat exercise was standardized using a metronome (60 beats / min) and each phase of the exercise lasted 3 seconds. The exercises were performed with two conditions; neutral (NT) and ECA. All participants were instructed to learn how to enhance abdominal core muscle activation using EMG biofeedback and they were instructed to keep ECA during the exercises as they could. IO/TA activation levels during the exercises were normalized to maximum voluntary contractions and expressed as %MVIC. Repeated measures of ANOVA was used for statistical analysis.
RESULTS: A significant effect of phases was found for dominant limb side IO/TA activation level in TLWS ($F(2,22)=5.87$, $p=0.009$) and in DLWS ($F(2,22)=4.43$, $p=0.02$). Enhanced IO/TA activation level was greater during static phase of the TLSQ compared to descending ($p=0.04$) and ascending phases ($p=0.01$). However, ECA was greater both in descending and the static phases compared to ascending phase ($p=0.01$, $p=0.02$, resp.) in DLWS. The effect of phase was not significant contralateral IO/TA activation levels during the exercises ($p>0.05$).
CONCLUSION: The present findings suggest that abdominal muscle activity on the dominant side is affected by phases during the squatting exercise while the other side (non-dominant) is not affected. Since abdominal core activation enhancement seems to be more achieved in static phase of the squat exercises, beginning lower extremity neuromuscular training with static squat exercises may be more useful to train abdominal core activation in individuals with weak core stability.

THREE-YEAR LONGITUDINAL TRANSFORMATION OF SPRINT MOTION CAUSED BY AWKWARDNESS IN EARLY ADOLESCENCE

KOKUDO, S.1, SANO, T.2, KAWAKATSU, S.1,3, KONDO, R.4, UEDA, K.5

1: KOBE UNIVERSITY, 2: SHIFUBA ELEMENTARY SCHOOL, 3: JSPS, 4: NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA, 5: MINATOGAWA COLLEGE

INTRODUCTION: The adolescent awkwardness of sprint was investigated from the speed decline (Bounen & Malina, 1988) and the motion deterioration through the age difference with cross-sectional data (Kokudo, 2017). Change of sprint motion caused by awkwardness shall be observed longitudinally. The purpose of this study was to investigate the longitudinal transformation of sprint motion during 3-year in early adolescence.
METHODS: The subjects were 110 children (56 boys and 54 girls) of 4-6th grade in 2016. Their intermediate (25-35m of 50m sprint) sprint speed (SS) were measured by sensor timer and their sprint motion (SM) was recorded from May 2016 to May 2018. Their height and weight information also collected through the yearly health check-up during April of each measurement year., Their forms were played in slow motion or frame-by-frame, and 2 investigators evaluated the checkpoints of observational sprint motion causal model (Kokudo, 2017).
The three years of data were pooled and categorical factor analysis and oblique rotation by promax criteria was applied to identify SM factors and factor scores.
Children were classified into 4 groups of SS development (SSD) pattern by cluster analysis using SS, yearly SS change (SSC) and SS acceleration (SSA). Repeated ANOVA was applied in each SM factor in order to investigate the difference of SM from 2016 to 2018 by SSD and sex.
RESULTS: Six factors were extracted and 55.8% of total variance was explained by these factors. Factor were interpreted as F1: arm-swing and trunk-twist motion, F2: weighting motion, F3: leg grounding preparation, F4: drive motion, F5: take off motion and F6: grounding motion, respectively.
Significant interactions between repeated measurement and SSD group were found on F3 ($F=3.12$, $p<0.01$) and F4($F=2.34$, $p<0.05$) in girls; the F3 score change of group-4, which SSC was large but SSA was negative, showed similar pattern as SSD change, The F4 score of group-3, which SS was low, SSC was large but SSA was mostly zero, was decline during 3 years. Significant main effect of the repeat was found in F1 ($F=8.93$ $p<0.01$) in boys; their scores were increased during 3 years. Significant main effects among SSD groups were found in F1 in boys ($F=4.74$, $p<0.01$) and girls ($F=6.17$, $p<0.01$) and F3 ($F=5.32$, $p<0.01$) in girls. It seems that the difference reflected running ability; high SS group showed high score. The awkwardness of sprint motion had not clarified yet in boys in this study.
CONCLUSION: Awkwardness of sprint occurs in drive motion in girls; however, it has not clear yet in boys.

INDIVIDUAL ANALYSIS OF MOVEMENT COORDINATION IN PISTOL SHOOTING

CHEN, H.H., CHUANG, K.L.

DEPARTMENT OF PHYSICAL EDUCATION, NATIONAL TAITUNG UNIVERSITY; BACHELOR PROGRAM OF ATHLETIC PERFORMANCE, NATIONAL TAITUNG UNIVERSITY

Introduction
To achieve precise and stable performance, the air pistol shooters must control their movement with extreme precision. Inconsistent results were seen in previous studies about how their movement was controlled. According to the hypothesis of Newell (1986) and the observation of Arutyunyan, et. al. (1969), it is assumed that movement coordination exist individual difference and related to the outcome

performance. The purpose of this study was to compare the movement coordination of good and bad shooting of individual shooters to unveil the relation between movement control and performance.
Method
Four air pistol athletes participated to perform 3 sessions of simulated competitions during which the 3D coordinates of upper limbs and gun and center of pressure (COP) were recorded. Displacement series were split up in slow drift and tremor components. Three of best and worst shots were selected in each session for comparisons. Amplitude and coordination of movement were estimated by standard deviation and principal component analysis.
Results
Though significant larger amplitude were found for limbs and gun in lateral and for COP in tremor, no significant difference was seen between good and bad shots in movement amplitude. Four components could explain more than 95% of variance. Significant delayed correlation was seen among principal components for drift while no correlation for tremor. While the contents of components showed individually different, the good shots showed smaller drift motion in lateral and distributed the activities of tremor to different direction and segments, in general.
Discussion
The low number and high correlated components of slow drift imply that the execution of voluntary pistol aiming may be governed by a low-dimensional control structure. Under the constraints of task and individual, varied patterns of movement coordination were showed. However, the coordination that can distribute the tremor activities properly induces good performance.

ARE THERE DIFFERENCES BETWEEN THE LEAD LIMBS DURING BLOCK JUMP-LANDING IN DIFFERENT DIRECTIONS?

MERCADO-PALOMINO, E., MOLINA-MOLINA, A., DELGADO-GARCÍA, G., ARAGÓN-ROYÓN, F., RICHARDS, J., BENÍTEZ, J.M., UREÑA, A.

UNIVERSITY OF GRANADA

INTRODUCTION: Volleyball-specific tasks such as jumping or landing need to be combined with fast movements to replicate real game situations, which demands a lot from the musculoskeletal system (1). Identification of injury risk factors between limbs during these tasks is essential for the development of targeted prevention programmes. Therefore, it is necessary to add jump-landing directions to determine the control of the lower extremities (2) by including the approach velocity and distance to replicate a normal block technique. Therefore, this study aimed to investigate the differences between the lead limbs when the player is moving to the dominant and non-dominant directions.
METHODS: Fourteen semi-professional female university team volleyball players (aged 20.4±2.1 years; height 171.24±3.3 cm; mass 65.6±6.3 kg) participated in the study. Twelve block jump-landings were performed from the left and right directions as fast as possible. Hip, knee and ankle kinematic and kinetic data were collected using an 8 camera motion-capture system (Qualisys Oqus, Sweden) and 2 force plates (Kistler Instruments, Hampshire, UK). Two Machine Learning methods, Artificial Neural Networks and Random Forest, were used to generate models from the dataset.
RESULTS: All models exhibited a predictive accuracy > 94% when we compared the lead limbs during jump-landing, indicating a difference in landing strategy in the dominant limb when moving in the non-dominant direction compared to the non-dominant limb when moving in the dominant direction.
CONCLUSION: The lead limbs during a block-jump landing demonstrated differences in movement strategy when moving in the different directions, these could be predicted with very high accuracy from the kinematic and kinetic data. These results highlight the importance of considering the movement strategies of the dominant and non-dominant limbs when considering injury risks during jump-landing. Coaches and trainers should be aware of the differences between limbs, and to ensure jump-landings in both directions are incorporated into training, which may help prevent injuries during competitive match situations.

CP-PM32 Cardiovascular: Young

EFFECTS OF UPPER-BODY RESISTANCE TRAINING VS. LOWER-BODY RESISTANCE TRAINING ON CENTRAL AND PERIPHERAL ARTERY STIFFNESS IN YOUNG ADULTS

KIM, J., KIM, M., LEE, R., HWANG, M.

INCHEON NATIONAL UNIVERSITY

INTRODUCTION: Resistance training is a typical exercise modality frequently prescribed to promote musculoskeletal and cardiovascular health. However, some previous findings indicate that whole body resistance exercise might play a negative role in vascular compliance or elasticity in young adults. Effects of resistance exercise on arterial stiffness can be different according to age, exercise intensity, and recruited muscle groups. However, there exist a handful of studies reporting the effect of upper-body resistance training compared with lower-body resistance training on arterial stiffness in young adults. The purpose of this study was to investigate the effect of 8 weeks of moderate to high intensity upper-body vs. lower-body resistance training on central and peripheral artery stiffness in healthy young adults.
METHODS: Twenty-eight young adults participated in this study and randomly assigned into three groups: upper-body resistance training (n=9, URT), lower-body resistance training (n=9, LRT), and control group (n=10, CON). Both URT and LRT performed the established body part-specific resistance training at 70~80% of 1RM, twice a week for 8 weeks. To assess central artery stiffness, both aortic pulse wave velocity (AorPWV) and augmentation index (AIx) were measured by SphygmoCor Xcel system. Peripheral artery stiffness was assessed by either arm (brachial to radial artery) pulse wave velocity (ArmPWV) or leg (femoral to posterior tibial artery) pulse wave velocity (LegPWV) measured by Doppler Flowmeters.
RESULTS: URT significantly improved AIx (4±3% vs. 0±3%, p=0.02), AIx@75 (-4±4% vs. -11±3%, p=0.04), ArmPWV (10.5±0.4 vs. 8.5±0.6 m/s, p=0.03). LRT did not present any negative effects on AorPWV, AIx, AIx@75 and LegPWV.

CONCLUSION: In conclusion, compared to LRT, URT is more beneficial to improve both central and peripheral artery stiffness in young adults.

PREVALENCE OF ARTERIAL HYPERTENSION AND ABNORMALITIES IN ECHOCARDIOGRAPHY IN YOUNG STUDENTS

REINER, B., OBERHOFFER, R., WEIL, J., SCHULZ, T.

INSTITUTE OF PREVENTIVE PEDIATRICS, TECHNISCHE UNIVERSITÄT MÜNCHEN

INTRODUCTION: Sudden cardiac deaths of athletes are alarming, but fortunately the fatal events are rare and the cases can be further reduced by a better understanding of the causes and mechanisms. Therefore, medical and sport associations recommend a regular pre-participation screening to minimize the risk of cardiovascular events and suffering from sudden cardiac death.(1) So far, the recommendations mainly focus on competitive athletes. But what about other young people, who are regularly physically active – such as sport students? Could they benefit of a systemic cardiovascular screening, too? The aim of this study is to early detect anomalies of vascular function and heart structure in first-year sport and health students to prevent later cardiovascular events.
METHODS: In total, 246 freshmen and first-year students (21.2±2.5years, 68.7%female) of sport or health sciences were recruited at our department from May 2017 until January 2019. Arterial blood pressure as well as central systolic blood pressure were assessed by Mobil-O-Graph®. All values of systolic blood pressure were categorized as recommended by guidelines (highly normal=130-139mmHg, hypertension stage I = 140-159mmHg). The intake of medication and drugs were registered. Further, an echocardiography and cardiopulmonary exercise test with exhaustion were performed by all participants.
RESULTS: 13.8% of the subjects showed highly normal blood pressure, while 7.3% were classified in hypertension stage I. None of them took blood pressure medications. The values were linked with sex ($p<0.001$), age ($p=0.031$), weight ($p=0.008$) and drugs ($p=0.027$). Arterial systolic ($p<0.001$) and diastolic ($p=0.008$) blood pressure, as well as central systolic blood pressure ($p<0.001$) were significantly higher in male than in female patients. Further, in male students diastolic blood pressure ($r=257$, $p=0.027$) and central blood pressure ($r=270$, $p=0.034$) were linked with exercise capacity.
14.2% of the students had abnormal findings in their echocardiography and were recommended to do a follow-up examination within the next one to three years. Out of them four students were recommended to see a cardiologist for further diagnostics and two had already a heart surgery.
CONCLUSION: Pre-participation screenings for young, physically active students seem to be useful and necessary to detect early anomalies and prevent long-term impairments. Blood pressure is often high in young people without their knowledge. Uncovered, these abnormalities can cause long-term damage and may increase the risk of cardiovascular events.

RELATIONSHIP BETWEEN VASCULAR COMPLIANCE AND BODY COMPOSITION, PHYSICAL FITNESS, AND DIETARY HABITS IN YOUNG PEOPLE: FOCUS ON THE DIFFERENCE BETWEEN VEIN AND ARTERY

MAEDA, K., IIMURA, Y., YOSHIZAKI, T., OUE, A.

TOYO UNIVERSITY

INTRODUCTION: Vascular compliance is thought to decrease as a result of aging, unhealthy lifestyle, and lack of exercise, and might lead to cardiovascular disease such as hypertension (1, 2, 3). Although physical activity and nutrient intake are considered to improve arterial compliance and have been investigated well, data on venous compliance is limited. Because of differences in structure and function between vein and artery, it is expected that factors related to venous compliance might also differ from those of arterial compliance. Thus, the purpose of this study was to investigate the relationship between body composition, fitness level, and dietary habits and venous and arterial compliance in healthy young people.
METHODS: Calf venous compliance (VCPL), arterial stiffness, body composition, fitness level, and dietary habits were assessed in healthy young participants (male = 45; 20.4 ± 0.2 yr, female = 53; 19.9 ± 0.1 yr). Calf VCPL was calculated as the first derivative of the cuff pressure-calf volume relation obtained by venous occlusion plethysmography during the cuff deflation protocol. Arterial stiffness was assessed using brachial-ankle pulse wave velocity (baPWV) measurements. Body composition was determined by bioimpedance analysis. Fitness level was based on muscle strength, agility, flexibility, muscular endurance, and whole-body endurance measurements. Dietary habits were evaluated from a self-administered diet history questionnaire.
RESULTS: VCPL was negatively correlated with body weight, body mass index (BMI), body fat mass, and body fat percentage in both female and male participants ($P < 0.05$); baPWV was positively correlated with BMI, body fat mass, and body fat percentage in only female participants ($P < 0.05$). VCPL was positively correlated with muscular endurance in only female participants ($P < 0.05$). BaPWV was negatively correlated with flexibility and total fitness level in both female and male participants ($P < 0.05$), and there was a negative correlation between baPWV and endurance in female participants ($P < 0.05$). Furthermore, VCPL was positively with retinol, vitamin K, folate, and several food groups in female participants, but baPWV was negatively correlated with retinol in female participants and with copper in male participants ($P < 0.05$).
CONCLUSION: Factors involved in body composition, physical fitness, and dietary habits related to vascular compliance might differ between vein and artery, and might have a sex difference in young people.

ASSOCIATIONS OF ANTHROPOMETRIC MEASURES AND FITNESS STATUS WITH CARDIOVASCULAR PARAMETERS IN PRIMARY SCHOOL CHILDREN

KIRCHHUEBEL, H., OBERHOFFER, R., BÖHM, B.

TECHNISCHE UNIVERSITÄT MÜNCHEN

INTRODUCTION: Pulse wave velocity (PWV) and central systolic blood pressure (CSBP) are well-established biomarkers of arterial stiffness. They can be used to identify subclinical atherosclerosis and to prevent cardiovascular events. Further, good fitness status is known to be an important protective factor in adults in respect of vascular stiffening. However, the association of both muscular and cardiorespiratory

fitness (CRF) with arterial properties in young children has been inconsistent. The aim of the present study was to investigate the relationship between anthropometrics, CRF, strength status, and arterial stiffness parameters in German primary school children.
METHODS: A total of 76 children from 6 to 11 years (63.2% males) were examined with regard to their anthropometrics, cardiovascular parameters, and fitness status. Peripheral and central aortic blood pressure as well as PWV were measured with oscillometry (Mobil-O-Graph). Aerobic capacity was measured using the 20m shuttle run test. Hand grip strength (HGS) as an indicator of overall muscle strength was determined with the Jamar Analogue Hand Dynamometer. For more detailed analyses, the study group was divided in subcohorts, namely a risk group including children with either abnormal blood pressure or high body weight, and a healthy subgroub.
RESULTS: Healthy children showed a positive association between PWV and body mass index (BMI) (p= 0.016) and CSBP and BMI (p= 0.033), respectively. HGS was positively associated with CSBP (left: p= 0.013, right: p= 0.015) and PWV (left: p= 0.008, right: p= 0.002), as well as shuttle run rounds were positively correlated to PWV (p= 0.038) in the whole cohort. No significant association of converted VO2max with arterial PWV were found. Multivariate regression models revealed no variable that emerged as an independent determinant of PWV and CSBP
CONCLUSION: This study has demonstrated that muscle fitness in young primary children is associated with higher PWV and greater CSBP. These findings provide new evidence that greater strength status is linked with worse arterial stiffness parameters in young children. It has also shown that an elevated BMI is linked with higher PWV, supporting the role of weight control in prepubescent children. The unfavourable association of better performance in the shuttle run test and arterial stiffness parameters needs further exploration and future research should reinforce the evaluation of underlying mechanisms concerning fitness and arterial elasticity in primary school children.

AN INTER-RELATIONSHIP BETWEEN CARDIOVASCULAR AND POSTURAL SYSTEMS IN APPARENTLY HEALTHY CHILDREN

PRATS-PUIG, A., CADELLANS-ARRONIZ, A., CAZORLA-GONZÁLEZ, J., HERNÁNDEZ-SERRANO, O., GACTO-SÁNCHEZ, M., FONT-LLADÓ, R.

UNIVERSITY SCHOOL OF HEALTH AND SPORT (EUSES), UNIVERSITY OF GIRONA, GIRONA, SPAIN

INTRODUCTION: During upright posture, skeletal muscles help maintain venous return and consequently regulates blood pressure homeostasis. Previous studies have reported a positive association between orthostatic changes of systolic and diastolic blood pressure with the centre of pressure in adults. However, studies in children regarding the association between the centre of pressure, blood pressure and obesity parameters are missing. The purpose of our study was to assess the association between the centre of pressure path length and cardiovascular (systolic and diastolic blood pressure) and anthropometric variables (waist, muscle mass, fat mass and BMI SDS) in apparently healthy children.
METHODS: The centre of pressure path length (Wii fit), systolic and diastolic blood pressure (Dinamp Pro 100) as well as muscle mass, fat mass (TANITA), waist and BMI SDS were assessed in a cohort of apparently healthy children (n= 171, 81 girls and 90 boys) with a mean age of 7.45 ± 0.33 included in the Physical Education, Health and Children (PEHC) Study. Associations between the centre of pressure path length and cardiovascular and anthropometric variables were assessed by Persons correlations following multiple regression analysis to adjust for confounding variables.
RESULTS: In our study, higher values for the centre of pressure path length for the dominant leg were associated with higher systolic and diastolic blood pressure (r=0.158; p=0.037 and r=0.165; p=0.033, respectively) and with higher values for the studied anthropometric variables [waist (r=0.235; p=0.002), percentage of fat mass (r=0.196; p=0.010), muscle mass (r=0.174; p=0.022) and BMI-SDS (r=0.190; p=0.013)]. No associations were seen either for non-dominant leg or bilaterally.
Interestingly, all the associations between the centre of pressure path length and cardiovascular [systolic and diastolic blood pressure (r=0.298; p=0.004 and r=0.234; p=0.027, respectively) and anthropometric variables [(waist (r=0.337; p=0.001), percentage of fat mass (r=0.322; p=0.002), muscle mass (r=0.268; p=0.010) and BMI-SDS (r=0.275; p=0.009)] remain significant only in girls.
In multiple regression analyses, girls' centre of pressure values contributed independently to systolic blood pressure (β= 0.198, p= 0.034) explaining 40.5% of its variance after controlling for age, height, percentage of fat mass and maturity offset.
CONCLUSION: These results suggest an independent effect of the centre of pressure path length on blood pressure as early as in childhood. Thus, providing more evidence for the inter-relationship between cardiovascular and postural systems.

EVALUATION OF CEREBRAL OXYGENATION IN MODERATE AND HIGH-INTENSITY CONSTANT-LOAD EXERCISE IN YOUNG ADULTS

PINNA, V., NUGHEDDU, G., DONEDDU, A., CRISAFULLI, A.

UNIVERSITY OF CAGLIARI

INTRODUCTION: The maintenance of adequate cerebral perfusion is crucial to ensure normal brain function during exercise. Recent studies have reported that cerebral oxygenation (COX) plays a key role in the perception of fatigue and performance as COX can be reduced during heavy strain (1). To better understand the mechanisms by which strenuous exercise impairs COX, it would be useful to evaluate COX by using near-infrared-spettroscopy (NIRS) (2). The aim of this study was to compare COX during two levels of constant-load exercise in young adults: one at moderate intensity (at the level of the first ventilatory threshold) and one at high intensity (at the level of the second ventilatory threshold).
METHODS: Eleven (11) male young adults (age 23.64 ± 3.86 years, height 172.5 ± 6.32 cm, body mass 71.29 ± 7.83 kg) agreed to participate in this study. They underwent a preliminary incremental cardiopulmonary test on a cycle-ergometer to assess their first (AT) and second (AnT) ventilatory threshold. Then, they performed two constant-load exercises pedaling at workload (W) corresponding to that of AT and AnT for 5 minutes. Respiratory gas exchanges were assessed by means of a gas analyzer (ULTIMA CPX, MedGraphics St. Paul, MN), whereas COX and peripheral oxygen saturation (O2SAT) were detected by using NIRS (Nonin, SenSmart X-100, Plymouth, MN, USA) and finger pulse oximeter, respectively.
RESULTS: Workload at AT and AnT was 168.57 ± 28.52 and 235.71 ± 38.77 W respectively. As expected, the two tests yielded different cardio-metabolic responses (VO2A 27.3 ± 5.4 ml/kg; VO2AnT 37.6 ± 7.4 ml/kg; heart rate AT 146.46 ± 17.25 bpm; heart rate AnT 168.69 ± 14.40 bpm). COX did not show any significant difference between tests (94.5 ± 18 % and 93.6 ± 20 % during AT and AnT test respectively). Differently, O2SAT was found lower at AnT as compared to AT (91.8 ± 6.3 vs 95.6 ± 2.7 % P= < 0.05).

CONCLUSION: Data obtained in the present study show that high-intensity exercise did not lead to any impairment in COX in young adults. Probably, this outcome can be related to the ability of regulatory mechanisms controlling brain circulation which successfully maintained an efficient oxygen supply even at intensity of AnT and in the presence of significant Hb desaturation.

AEROBIC FITNESS: INFLUENCE ON CARDIOVASCULAR HEALTH AND CARDIAC AUTONOMIC CONTROL IN YOUNG COLLEGE STUDENTS

DE SOUSA, A.F.M.1, ABDALA, A.T.1, FLOR, G.K.1, CRUZ, L., OLIVEIRA-SILVA, I.2, VIDAL, S.E.1

1.UNICEPLAC, BRASILIA, BRAZIL., 2. UNIEVANGELICA, ANAPOLIS, BRAZIL

INTRODUCTION: College students have a routine of academic activities that require high cognitive performance, leading to increased psychological and cardiovascular stress. Cardiovascular stress reduces heart rate variability (HRV), which is a simple and indirect method for monitoring cardiac autonomic control. Resting heart rate (RHR) may represent an indicator of cardiovascular health, and previous studies have shown that body composition is an important variable that can influence both cardiovascular health and cardiac autonomic control. Greater aerobic fitness is positively related to improved cardiovascular health and better cardiac autonomic control. The aim of the present study was to verify the influence of different levels of aerobic fitness (higher vs. lower) on cardiovascular health and cardiac autonomic control of young college students.
METHODS: Twenty male college students (aged 21.2±2.1 years) participated. Aerobic fitness (VO2max) was estimated according to the Astrand nomogram and compared with normative values proposed by the American College of Sports Medicine; for division between groups, to be classified above or below regular aerobic fitness was the cut-off, therefore, participants in higher aerobic fitness group had regular, good or excellent aerobic fitness, and lower aerobic fitness group had weak or very weak aerobic fitness. Body mass and stature was used to calculate body mass index (BMI) and skin folds were performed. Cardiac autonomic control was assessed by means of the HRV time domains (e.g. RMSSD and SDNN) and the short (SD1) and long (SD2) axes from Poincarè Plot, and RHR was also recorded, both at rest, in the sitting position for 10 minutes with a cardiac monitor (RS800CX, Polar Electro Oy, Kempele, Finland), and the final 5min were used. Normality was assessed and students t-test and Pearsons r were performed. Significance level of $p < 0.05$ it was adopted.
RESULTS: Participants were divided into higher and lower fitness groups according to VO2max (46 ± 6 vs. 31 ± 2). The higher group compared to lower group demonstrated greater cardiac autonomic control [SDNN (74.1 ± 36.3 vs. 47.9 ± 12.4); RMSSD (55.4 ± 32.4 vs. 33.9 ± 13)] SD1 (39.2 ± 22.9 vs. 24 ± 9.2); SD2 (96.8 ± 46.8 vs. 63.1 ± 16.1)] and lower RHR [65.5 ± 10 vs. 79.8 ± 11.3] respectively. VO2max had a moderate and negative correlation with RHR ($r = -0.5$; $p = 0.03$). In addition, there was no difference in the sum of skinfolds [103.5 ± 39.2 vs. 133.6 ± 51.2] and BMI [24.7 ± 2.5 Vs. 24.9 ± 4.4] between groups.
CONCLUSION: Participants in the higher aerobic fitness demonstrated greater cardiac autonomic control and lower RHR compared to the lower aerobic fitness participants. Although there is no statistical difference, the lower sum of the skinfolds of the higher group may have contributed to the results. However, greater aerobic fitness may favor cardiac health among young college students.

HIGHER GOLF SKILL WAS CHARACTERIZED BY PSYCHOMOTOR REFINEMENT IN COGNITIVE, ATTENTIONAL AND MOTOR CONTROL PROCESSES.

HUNG, T.M.1, WANG, K.P.1, CHENG, M.Y.2, CHEN, T.T.1, HUANG, C.J.3

1. NATIONAL TAIWAN NORMAL UNIVERSITY 2. BIELEFELD UNIVERSITY 3.UNIVERSITY OF TAIPEI

INTRODUCTION: Expert novice comparison studies in skilled performance have provided insight for the understanding of control processes underlying motor expertise. This study went one step further to focus on the cortical activation differences between two groups of golfers with small skill gap.
METHODS: Twenty highly skilled (experts, handicap 4.25±1.99) and 18 less skilled golfers (amateurs, handicap 32.44±6.21) were recruited to perform 60 putts while EEGs were recorded. The EEG alpha of the last two second prior to the putting movement were compared between the two groups.
RESULTS: Compared with amateurs, experts showed (1) lower alpha 2 power at Pz and T4 in T2, (2) lower alpha 2 power at Fz, Cz, and T4 in T1, (3) lower alpha 2 coherence at Fz–T3 and Fz–T4. In addition, alpha 2 coherence at Fz–T3 and Fz–T4 in T2 were higher than T1 in experts.
CONCLUSION: The present study showed that several cortical activities as revealed by EEG measures could differentiate highly skilled golfers from the less skilled ones. Specifically, the highly skilled golfers were characterized by increased regional gating of alpha 2 and less interference of verbal-cognitive processing and visuo-spatial processing before putting. These findings provide evidences for the refinement of psychomotor efficiency for the highly skilled performer, which could shed light on the facilitation of expertise even for skilled golfer to reach to the top level.

HOW DO AGE, SPORTS DISCIPLINE AND SCOPE OF TRAINING INFLUENCE SELECTED CARDIOPULMONARY EXERCISE PARAMETERS IN YOUNG ATHLETES ?

APPEL, K., ENGL, T., OBERHOFFER, R., SCHULZ, T.

TECHNICAL UNIVERSITY OF MUNICH

INTRODUCTION: Cardiopulmonary exercise testing (CPET) is a common tool in pre-participation screenings for elite athletes to detect physiological and pathological adaptions to exercise. Research in Pediatric exercise testing is mainly indicated in medical contexts (e.g. congenital heart disease, pulmonary hypertension and cystic fibrosis), Data for young athletes are still rare. The aim of this study was to examine the influence of age, sports discipline and scope of training of young athletes on selected CPET values.
METHODS: 473 young athletes (419 male) were examined from 2016 to 2018. All underwent pre-participation screening including anamnesis, physical examination, ECG (resting and stress), echocardiography and CPET via ramp test on a cycle ergometer. Youth athletes (age: 14.10 ± 2.14 yrs, height 169.76 ± 14.16 cm, weight 58.65 ± 15.32 kg, body surface area: 1.66 ± 0.28 m^2) participated at least 5 hours per week in their main type of sport (8.98 ± 3.02 hrs). Sports disciplines were classified according to the percentage of VO2peak (A-

C) and MVC (1-3) involved during exercise (1). As data was limited for girls, analysis was only executed for boys for VO2peak, maximum power (Pmax), maximum RQ (RQmax) and maximum heart rate (HRmax).
RESULTS: Young male athletes had a Pmax of 4.60 ± 0.48 W/kg with HRmax 186.55 ± 11.06 bpm and a VO2peak of 48.70 ± 7.11 (mlO2/min)/kg. Athletes of endurance-dominant sports, like soccer (C1: >70% VO2peak,1: <20%MVC), showed higher VO2peak values as sports with equal amounts of force and endurance, like volleyball (p<.005). Also C1 athletes had higher values in maximum power as B1 athletes (B: 40-70%VO2peak). RQ max values were higher in B1 athletes compared to C1 and C2 (p<.005), HRmax values did not differ between sport disciplines (p>.05).
Multiple regressions showed that age and sports discipline do have a significant impact on CPET values HRmax (F(2.350)=4.13, p=.017, n=350), RQmax (F(2.351)=11.90, p=.000, n=351) and Pmax (F(2.352)=4.95, p=.008, n=352). Age positively influences Pmax and RQmax (r=.15; p<.01; r=.21, p<.01), but not VO2peak. Scope of training and agegroup positively influence RQ max (r=.43). A significant correlation between HRmax and VO2peak could be found (r=.14, p<.05).
CONCLUSION: Results show that age and sports discipline affect cardiopulmonary fitness, especially regarding maximum power and maximum RQ (as an indicator for exhaustion during exercise). With increasing age and sports disciplines, involving higher % of VO2peak, young athletes are able to realize higher performance. VO2peak values seem to be independent of age and sport discipline, but may be influenced by other factors, like body weight or fat free mass. They are in line with current normative data, but subjects in our study seem to be able to realize higher performance values on a cycle ergometer (2).

PL-PS04 The importance of circadian rythm for athletic performance and skeletal muscle health

THE INTRINSIC MUSCLE CLOCK AND MUSCULOSKELETAL HEALTH

ESSER, K.
UNIVERSITY OF FLORIDA

Circadian biology is emerging as a fundamental factor of human health but is also providing insight into human athletic performance. At the core of circadian rhythms is the molecular clock mechanism. This mechanism is found in all cells throughout the body and is defined by a transcription-translation feedback loop with the gene, Bmal1 encoding a core molecular clock transcription factor. My lab has been studying the role of the endogenous molecular clock mechanism in skeletal muscle using different in vitro and in vivo model systems. For this talk, I will focus on our work in which we show that disruption of Bmal1 in adult skeletal muscle leads to muscle weakness in the absence of atrophy. We demonstrate that the master myogenic regulatory factor, MYOD1, is directly regulated by the clock. In addition MyoD1 functions synergistically with BMAL1 to regulate a daily program of muscle gene expression. When the muscle clock is disrupted we find changes in sarcomere structure and sarcomeric protein expression that are linked to diminished force output. This emerging area of circadian rhythms and the molecular clock in skeletal muscle holds potential to provide significant insight into intrinsic mechanisms of the maintenance of muscle quality and function as well as potentially identify time of day variances that could alter training and recovery strategies for athletes.

CIRCADIAN CONTROL OF DIURNAL PERFORMANCE PATTERNS IN ATHLETES

BRANDSTAETTER, R.
CLOCKWISE

Circadian rhythms have been shown to regulate key physiological processes involved in athletic performance. Previous studies showed personal best performance of athletes to occur in the evening across different sports. Contrary to this view, we identified peak performance times in athletes to be different between human 'owls' and 'larks', i.e. individuals with well documented genetic and physiological differences that result in disparities between their biological clocks and how they entrain to exogenous cues, such as the environmental light/dark cycle and social factors.
Peak performance occurred at midday in early circadian phenotypes, in the afternoon in intermediate circadian phenotypes, and in the evening in late circadian phenotypes. We found time since awakening to be the major predictor of peak performance times rather than time of day, as well as significant individual performance variations in the course of one day. Following a specific non-photic phase-shifting protocol, relevant sleep/wake parameters as well as peak performance times shifted to earlier times of day suggesting intrinsic circadian mechanisms as physiological regulators and demonstrating the impact of circadian entrainment on athlete performance.
Our novel approach that combines the use of an athlete-specific chronometric test, longitudinal circadian analysis, physical performance tests, and phase-shifting interventions, allows a comprehensive analysis of the link between the circadian system and diurnal performance variation. We establish that the correct evaluation of an athlete's personal best performance requires consideration of the entrainment status of the circadian system and that optimal performance can be adjusted by entrainment of the circadian clock.

Biomechanics

PRINCIPAL COMPONENT ANALYSIS FOR THE AMATEURS' GOLF SWING WITH SENSORS ON WHOLE BODY SEGMENTS

PENG, H.

CHINESE CULTURE UNIVERSITY

INTRODUCTION:Golf swing is accomplished by complex rotation of whole body segments and continuous movement of joints. Previous researchers represented motion as temporally quantized vectors of joint angles, and performed a principal component analysis (PCA) on the resulting database of motion vectors to reduce the dimensionality (1). A functional swing plane (FSP) of golf swing is a mechanically meaningful plane and biomechanical properties in the FSP can mostly characterize golfer's swing (2). The purposes of the study were to investigate the segments orientation variables in the FSP during golf swing and create a new set of orthogonal variables that can describe the majority of variance in the original dataset using the PCA.
METHODS: 20 amateur golfers (14 male, 6 female; age = 41.3 ± 10.9 yrs.; height =170.0 ± 9.3 cm; weight = 70.8 ± 12.0 kg; handicap = 18.1 ± 6.7) were participants. They performed 15 successful shots with a 7-iron golf club in a simulated screen golf system (Golfzon Co., LTD., South Korea) chamber. A successful shot was defined as the golf ball being in a green area which was set in a practice mode of the screen golf system. 18 inertial measurement units (MVN, Xsens North America Inc., Netherlands) were put on the participant's body and club, and the orientation variables were analyzed using MVN motion analysis software. The variables were analyzed at 3 events in the FSP which were mid-downswing (MD), ball impact (BI) and mid-follow-through (MF). The MD was defined as the club shaft parallel to the horizontal plane during downswing, BI was defined as the instant of the club hitting the ball, and MF was defined as the club shaft parallel to the horizontal plane during follow-through. The segments were grouped into a upper body (head, neck, T8, T12, L3, L5, golf club, right and left shoulder, upper arm, forearm, and hand) and a lower body (pelvis, right and left upper leg, lower leg, foot, and toe) to conform with the number of variables/trials ratio requirement of PCA in the statistics. PCA was practiced using a SPSS 20.0 (SPSS Inc., Chicago, IL, USA) software.
RESULTS: The PCA model consisted of three principal components accounted for 74.93% and 79.66% of the total variance as critical factors for assessing the golf swing on the upper and lower body, respectively. The first component on the upper body consisted of almost whole upper body segments except the golf club, left forearm and hand orientation at the MF. The first component on the lower body consisted of right upper leg, lower leg, foot, toe, and left upper leg and lower leg at MD, right upper leg, lower leg, foot, toe, and left upper leg and lower leg at BI, right lower leg, foot, toe, and left upper leg and lower leg at MF.
CONCLUSION: Based on the results in the present study, the new set of orthogonal variables would be the upper body segments orientation at MF, and right lower leg, foot, toe, left upper leg and lower leg orientation in the FSP.

KNEE BIOMECHANICS BEFORE AND AFTER ANTERIOR CRUCIATE LIGAMENT (ACLR) RECONSTRUCTION DURING RUNNING

ALARIFI, S., HERRINGTON, L., JONES, R.

UNIVERSITY OF SALFORD, SALFORD, UK

INTRODUCTION:The kinematics and kinetics between before and after ACL reconstruction have been compared in various studies. However, the different kinematics and kinetics, may results in different performance abilities during running. Moreover, this may have consequences for long-term rehabilitation and return to sport for the individual. Currently, there is no research detailing kinematics and kinetics before and after ACL reconstruction during running. Therefore, the purpose of this study is to compare the knee kinematics and kinetics before and after for ACLR individuals and a control group during running.
METHODS: Six individuals (4 male and 2 female, mean +/- standard deviation age, height and mass are 22.3 ± 5.7 years, 1.70 ± 0.08 m, 68 ± 10.9 kg) who had sustained an ACL injury and were on the waiting list for reconstruction were recruited to the study, were compared with six healthy subjects 4 male and 2 female, 24.1±3.9 years; mean height, 1.72±0.06 m; mean mass, 65.8±12.5Kg). Each participant underwent a before and 3,6 months after ACLR assessment. A twelve-camera Qualisys motion analysis system (Qualisys AB, Sweden, AMTI, USA, 240 Hz), with an AMTI force platform (1200 Hz) embedded in the running track floor, was used to collect the kinematic and kinetic data. Subjects ran along a twenty two metre runway at a self-selected speed, which was recorded with timing gates with no significant deference in running speed between ACLR and healthy subjects observed. The contact phase (initial contact to toe off) of five trials was normalised to 100% of stance and averaged for each condition.
RESULTS: The running speeds were not significantly different between the two groups ACLR 3.20±0.23 m/s, healthy 3.19±0.33 m/s ($p > 0.05$). The kinematic and kinetic results are shown in Table 1. The peak internal knee extensor moment demonstrated a significant reduction in the injured limb for the ACLR group compared to the healthy group before, and three and six months after, ACLR ($p=0.02$; effect size 1.06, $p=0.01$; effect size 1.06, $p=0.02$; effect size 1.06 respectively). For all other kinematic and kinetic variables, the results show no significant differences in the ACL injury participants measured before, and three and six months after, reconstruction surgery.
CONCLUSION: This study has revealed that before and three and six months following ACL reconstruction, the athletes in this study showed some specifically altered knee joint kinematics and kinetics. The reduction in knee extensor moment and knee flexion angle was in an effort to reduce or avoid contraction of the quadriceps; this is called 'quadriceps avoidance'. However, these reductions will decrease the patella contact area and this will increase the patellofemoral contact stress over time; therefore, repetitive movements may contribute towards patellofemoral disorders, thereby increasing the risk of degenerate joint disease, which is commonly found post-surgery.

CHARACTERISTICS OF STROKE PARAMETERS DURING THE START PHASE FOR SPRINT SPEED SKATERS

YUDA, J.1, YOKOZAWA, T.2

1: JAPAN WOMEN'S COLLEGE OF PHYSICAL EDUCATION, 2: JAPAN INSTITUTE OF SPORT SCIENCES

INTRODUCTION:Speed skaters can increase the skating velocity by pushing perpendicularly to the gliding direction of the skate (1). A running-like technique is adopted instead of a gliding technique during the start phase in a speed skating race. This study identified characteristics of stroke parameters during the start phase of a sprint speed skating race for development of performance.
METHODS: Sixteen skaters (mean ± SD, height: 1.70 ± 0.04 m, weight 67.6 ± 5.8 kg, age: 19.3 ± 2.8 y) provided informed consent and served as study subjects. Skaters participated in a 500-m speed skating competition in Japan or a time trial. They were videotaped with 2 synchronized high-speed video cameras (250 fps) positioned at the first part (first 10 m of the start) of the 500-m race; the recorded images were analyzed using a panning direct linear transformation technique. The three-dimensional coordinates of the segment endpoints and blades were determined to calculate the kinematic variables during the 5 steps (strokes) after the gun-shot.
RESULTS: There was a significant positive relationship between goal time (37 s 30 ± 1 s 09) and split time at 100-m (10 s 10 ± 0 s 26) in the 500-m race (mean ± SD, $r=0.908$, $p<0.001$). Although forward velocities of the center of mass increased gradually from the first to fifth stroke, stroke frequency remained steady during the start phase. There were significant negative relationships between forward velocities of the center of mass for each stroke except the first stroke and split time at 100-m. However, there was no significant relationship between stroke frequency and split time at 100-m in these strokes. On the other hand, significant relationships were observed in the first stroke. In the first stroke (from the instant of left blade off to that of left blade on), although there was no significant relationship between forward velocity of the center of mass and split time at 100-m, a significant positive relationship between stroke frequency and split time at 100-m was observed. In addition, a greatly significant negative relationship between forward displacement of the center of mass in the first stroke and split time at 100-m was observed.
CONCLUSION: This study suggested that gradual increase in the forward velocities of the center of mass with a high stroke frequency for each stroke during the start phase was an important factor for the improvement in sprint performance of speed skating. However, during the first stroke, this study suggested that skaters should increase the forward displacement of the center of mass by pushing the ice with effective extension of the right supporting leg regardless of the time taken for this stroke.

INVESTIGATION FOR THE MAXIMUM ANAEROBIC POWER PROFILE DEMAND ON THE ALPINE SKIERS

HOSHINO, H.

HOKUSEI GAKUEN UNIVERSITY

INTRODUCTION:Alpine skiers require both aerobic and anaerobic capacity particularly for explosive power and stretching-shortening cycle exercise performance capacity (Raschner et al. 2013). We classified the power characteristics of the force velocity relation generated during counter movement jump utilizing various additional loads generating two divergent profiles: speed type and force type (Hoshino 2013). The purpose of this study is to clarify the force-velocity characteristics of alpine skiers by classifying the maximum anaerobic power into force type and speed type by brief dynamic exercise using a bicycle ergometer which excludes the stretch-shortening cycle. In other words, we will clarify whether one power profilespeed or force typeare more prevalent or desirable for successful alpine athletes.
METHODS: This study consisted of seven subjects in alpine skiers. Maximum anaerobic power tests were measured at the using a Power Max V II stationary bike. Subjects performed 10-second pedaling at 3%, 5%, 7.5%, 9%, 11%, 13%, 15% load per body weight. The rest period between each pedaling exercise was 2 minutes. Maximum anaerobic power was measured three times: at the end of the 2017 competitive season (June 2017), at the beginning of the 2018 competitive season (September 2017), and at the end of the 2018 competitive season (June 2018).
RESULTS: The average power values for each % load studied and the resulting power profiles indicative of speed and force types. The averages of the seven athlete's maximum anaerobic power and corresponding load values obtained during the three trials
CONCLUSION: The maximum anaerobic power values at the end of the two studied competitive seasons than the values obtained at the end of the summer training session. The data suggests that competitive alpine skiing develops force type power, while off-season training develops speed type power. It seems that force type power development would best enhance alpine skier performance.

TIME ANALYSIS OF THE GIANT SLALOM TURN IN SNOWBOARDING

CIACCI, S.1, SIMSIG, M.1, SEMPRINI, G.1, NIGRO, F.1, CORTESI, M.2, FORNI, M.3, MANGIA, A.3, FANTOZZI, S.3

UNIVERSITY OF BOLOGNA

INTRODUCTION:Snowboarding is an increasingly popular sport, but it has been little studied so far, especially regarding the biomechanical characteristics (1). Most previous research concerned injury occurrence, the physiological profile of the snowboarding athletes (1) and dynamic variables characterizing the turn (2,3). Therefore, the aim of this study was to compare the turn technique of the snowboard giant slalom between elite and experienced recreational athletes, to improve the knowledge of performance factors and to provide suggestions to athletes and coaches.
METHODS: Eight male snowboarders, four belonging to the Italian Snowboard National Team (EA, age 27±3.2y, height 1.80±0.10 m, mass 83.4±4.3 kg) and four experienced recreational athletes (RA, age 41.5±5.5 y, height 1.76±0.03 m, mass 89.0±12.2 kg) were analyzed during two performance on a snowboard slope (14 gates spaced at 21 m, 200m total descent). Eight wearable inertial and magnetic measurement units (APDM Opals, 128 Hz) were used for data collection. The sensors were fixed on sternum, sacrum, thigh, leg, toe of ski boot (right and left). Snowboarders were filmed when passing through the first 4 gates using a video camera (JVC full HD, 250hz) to compare the video recordings and the inertial sensor signal, and to define an algorithm to identifies automatically the transition of the gate and the change of the ski edge of all turns. These events were used to divide the turn in 4 phases: from change of ski edge to gate (T1) and from gate to change of ski edge (T2). Each event was identified for the backside-B and frontside-F turn, defining this way T1B, T2B, T1F, T2F respectively.
RESULTS: Concerning time variables, EA showed shorter and more consistent times than RA in all turn phases (T1B 0.89±0.18s vs 0.99±0.11s, T2B 0.97±0.21s vs 1.53±0.50s, T1F 0.65±0.19s vs 1.23±0.3s, T2F 0.97±0.19s vs 1.31±0.22s), with significant differences ($p<0.05$) for all comparisons, with the exception of T1B. Also, the times of the total turn in B (0.92±0.19s vs 1.24±0.44s in EA and RA respectively) and in F (0.78±0.21s vs 1.25±0.24s in EA and RA respectively) were significantly shorter in EA than RA ($p=0.03$ and $p=0.001$ for B and F, respectively). T1 was shorter than T2 both in B and in F, but this difference was not statistically significant.

CONCLUSION: As expected, EA completed all the phases of the turn more quickly than RA. This difference was noticeable during the F turn, especially in the T1 phase, more evidently than in B. In fact, as confirmed by the coaches of the Italian National Team, to perform an optimal F technique, highly developed technical skills are needed. Moreover, EA showed, for all variables, a lower variability and a higher repeatability than RA. The results of this study suggest that, in attempt to improve the performance, it is overall necessary to enhance F technical skills.

ARM-STROKE DESCRIPTORS VARIABILITY DURING 200-M FRONT CRAWL SWIMMING

CORTESI, M.1, FANTOZZI, S.2, BARTOLOMEI, S.3, CIACCI, S.3, SEMPRINI, G.3, NIGRO, F.3, GATTA, G.1
UNIVERSITY OF BOLOGNA

INTRODUCTION:The arm-stroke cycle in swimming is characterized by temporal technique descriptors: the swimmer adjusted the time spent in each of the four arm-stroke phases (entry-, pull-, push-, recovery-phase) and the model of inter-limbs coordination (IdC) to achieved performance objectives. Recently, the use of inertial and magnetic measurement units (IMMUs) has got much interest in sports applications like swimming: IMMUs monitored the swimming action continuously without specified spatial limitation and do not require long-time post-processing and complex experimental setup. Therefore, the aim of this study was to investigate through IMMUs how elite swimmers adapt the pattern and variability of their arm-stroke temporal descriptors between (intra-trial) and within (intra-lap) the 8 laps of 200m front-crawl.
METHODS: Eight national-level male swimmers performed one 200m front-crawl at maximal effort in a 25m pool. Three synchronized underwater cameras (GoPro Hero 4) were placed on a sagittal view to recognize the intra-trial variability of velocity (VEL), stroke rate (SR) and stroke length (SL). Using IMMUs (APDM Opals, 5 units, 128 Hz) and validated algorithms (1) the variability of temporal technique descriptors (6 ± 1 cycle x swimmer x lap) were assessed. The algorithms identified the start events of the arm-stroke phases duration and IdC (time lag between the start of the pull phase and the end of the push phase for each limb). All temporal descriptors were expressed as a percentage of the complete duration of the stroke cycle. The intra-trial and intra-lap effects for each independent variable were examined using one-way ANOVAs and Fishers LSD corrections.
RESULTS: Significant and moderate to strong decrease of VEL, SR and SL for intra-trial comparison was found (mean 1.47 ± 3.55 m·s-1, $p < 0.001$, $\eta2 = 0.80$; mean 34.4 ± 3.5 cycles·min-1, $p < 0.001$, $\eta2 = 0.41$; mean 2.58 ± 0.27 m, $p < 0.001$, $\eta2 = 0.68$, respectively). A stable pattern along the 8 laps of the 200m for IdC and relative duration of each stroke phase was confirmed by the no significant intra-trial difference ($p > 0.05$). Significant and moderate main effect were found in intra-lap changes for IdC ($p = 0.002$; $\eta2 = 0.59$) with significant decrease ($p = 0.003$) in last 2 cycles of lap (-19.9 ± 0.9 %) compared to the first two (-22.3 ± 1.8 %). Then, the IdC remained stable within the lap (catch-up model) despite significant decrease in absolute value during effort. No significant variations were found for intra-lap comparison of each stroke phases duration.
CONCLUSION: Generally, the temporal technique descriptors remained stable during an all-out 200-m front-crawl swimming. The high-level swimmers were able to reproduce the same temporal technique descriptors during middle-distance event despite the decrease of velocity, stroke rate, and stroke length. Results indicated the IMMU technology as a viable option to recognize the variability of temporal technique descriptors during swimming trial.

THE MAXIMAL JERK SPEED IS A HIGH PREDICTOR OF THOROUGHBRED PERFORMANCE.

POINSARD, L., MOLINARI, C., PALACIN, F., KORALSZTEIN, J.P., BILLAT, V.L.
UNIVERSITÉ DEVRY VAL DESSONNE

INTRODUCTION:Until now, in human, the jerk has been examined under the concept of minimum jerk-model to be associated with the economy (running economy) which is a high predictor of running performance. Indeed, the smoothness of the locomotion and its trajectory could be quantified as a function of jerk, which is the derivative of acceleration and has been correlated with running economy. Hence, jerk is the third derivative of location (i.e. position). In several cases, natural biological trajectories are smooth. The minimum-jerk model1 assumes that biological movement is optimal in a precise mathematical sense, i.e. it is the smoothest possible. Indeed, the minimum-jerk model with via-points (several fixed points for example) minimizes the jerk along all the trajectories going through the via-points. The constrained minimum-jerk model2 assumes that the natural biological trajectory following a predefined path minimizes the jerk among all the trajectories following this path. Trajectories that we considered here are the whole body horse trajectories during a canter. Here we utilized the jerk as a specific galloping marker of horse strength and we hypothesis that the ability of horse to accelerate again at a very high-speed > 50 km.h-1 could be a high predictor of his performance (ranking on distance).
METHODS: 18 Thoroughbred (5.2 ± 1.6 years) (Maisons-Lafitte, France) were equipped with a HR monitoring system and an accelerometer (Polar heart-rate chest Equine belt with Teampro sensor, Polar Electro Inc, Kempele, Finlande) the training sessions over a year. Acceleration, HR, and speed were measured during the typical acceleration training. It consists in achieving a constant acceleration over 1000 meters until reaching the maximum horse speed of the day. The training sessions were all done on the slopes of the France Galop complex in Maisons-Laffitte (Yvelines, 78, France).
RESULTS: Here we showed that it was possible to get a discriminating factor of performance in thoroughbred without any need of testing but using the usual training as a 1000 meters accelerating bout. Furthermore, this bout was shown to be performed at a remarkably constant acceleration ($R2 = 0.004$, $P = 1$). However, at the end of this acceleration phase the jockey succeeded in getting a re-acceleration allowing determining a maximal speed reacceleration named the maximal speed Jerk. This allowed to use this speed where the acceleration plateaued, for estimating the horse ranking in a delay of 1 week prior the race.
CONCLUSION: Here we sought that thanks to the ability of the Jockey to perform a 1000m bouts at a constant acceleration (in a same way as the ability of human to control a self-pace acceleration in his proper run), this allowed to get a speed when acceleration plateaued and to use this "maximal speed Jerk" as a predictor a performance.

THE EFFECT OF TEMPORAL AND SPATIAL ANTICIPATION ON BAT SWING SPEED IN BASEBALL

KIMURA, M., YAMAMOTO, M., NIGORIKAWA, T.

**;TOKYO POLYTECHNIC UNIVERSITY, **; RIKKYO UNIVERSITY*

INTRODUCTION:In baseball, there are reportedly two ways batters can control the timing of their swing: modulation of the time of onset of the batting action and modulation of the action time after the onset of the batting action (1). In the latter case, any required corrections to the batting action will likely slow the swing speed. In addition, the batter needs to predict not only the timing of the hit, but also the course that the ball will take. It may therefore be conjectured that the bat swing speed (BS-S) will become slower when the batter is required to make the dual prediction of hit timing (temporal anticipation: TA) and course (spatial anticipation: SA). The aim of the present study was to investigate the effect on BS-S while batters carried out batting actions with a combination of TA and SA tasks.
METHODS: The subjects were seven male athletes from the Kanagawa University Baseball League, Japan (age 18–22 years, ≧12 years of baseball experience). The batting action TA and SA tasks were presented to the subjects using a photoreactive time measuring device. The subjects were instructed to adopt a batting posture and to hit a ball on a batting tee using a swing with maximum force immediately after presentation of a light stimulus indicating the onset of the batting action. For BS-S, a speed gun dedicated to measuring the swing speed of the wooden bat was used. There were four batting action prediction tasks: A) both TA and SA possible (Ta-Sa), B) only SA possible (T-Sa), C) only TA possible (Ta-S), and D) neither SA nor TA possible (T-S). The subjects carried out 16 swings for each task, for a total of 64 swings. Mean BS-S for each task was calculated for the seven subjects, and differences in the mean BS-S between the batting action tasks were investigated by means of a one-way analysis of variance (ANOVA).
RESULTS: The BS-S values for maximum force swing with no batting action tasks (MaxBS-S) ranged from 108 to 125 km/h. Mean values for BS-S with batting action tasks were: Ta-Sa, 105.2±6.5 km/h (91.0% MaxBS-S); T-Sa, 100.2±4.5 km/h (85.5% MaxBS-S); Ta-S, 98.1±4.5 km/h (84.1% MaxBS-S); and T-S, 91.7±6.6 km/h (81.1% MaxBS-S). There was thus a trend toward slower BS-S with increasing difficulty of TA and SA prediction. The results of the one-way ANOVA showed significant differences between the mean BS-S values for the four batting action tasks ($p<0.01$).
CONCLUSION: The BS-S of batters for the tasks in the present study became slower in the order of Ta-Sa>T-Sa and Ta-S>T-S. This implies that the batting strategies of batters with respect to TA and SA affect BS-S.

MODERATE TO THE HIGH CORRELATION BETWEEN THE ACCELERATION AND GROUND REACTION FORCE ON CERVICAL 7 FOLLOWING VARIOUS JUMPING MOVEMENTS IN WATER AND ON LAND

CHIEN, K.Y., CHANG, W.G., LIOU, R.J., CHEN, W.C.

NATIONAL TAIWAN SPORT UNIVERSITY, UNIVERSITY OF TAIPEI,

INTRODUCTION:It has been demonstrated that the vertical peak acceleration (ACC) of the accelerometer has a positive correlation with the peak ground reaction force (GRF) of the force plate, and an accelerometer can be used to precisely estimate GRF (1, 2). However, the correlation between the ACC and the ground reaction force (GRF) in water is still unclear. Moreover, it is quite difficult to completely control the body to fall on a limited area of the force plate when performing consecutive jumps. Therefore, it is not feasible to use only the force plate to obtain the precise impact data during continuous-jump. The purpose of this study was to investigate the correlation between the ACC and GRF when participants worn ACC on cervical 7 (C7), lumbar 5 (L5), and 3 cm above the medial ankle (Ankle), respectively, to conduct single jump, and continuous jumps in the water and on land.
METHODS: Sixteen healthy females the ages from 20-30 years old (height = 158.6±4.97cm; body mass = 54.8±8.33 kg) were as participants. They stood on a force plate to perform 5 types of single jump including of squat jump (SJ), lunge jump (LJ), jumping opening legs and arms (JOLA), counter movement jump (CMJ), single-leg jump (SLJ) and five-times continuous jumps of CMJ in water or on land on separately two days. Participants worn ACC on C7, L5, Ankle and stood on a force plate to jumping, captured the ACC and GRF parameters in the sagittal, frontal and horizontal plane. Pearson's product-moment correlation was analyzed the correlation between total ACC from three dimensions and the resultant GRF in water and on land.
RESULTS: In water environment, single jump of CMJ, JOLA, SJ, SLJ were shown high correlation (r = .921, r = .829, r = .833, r = .812) on C7. The high and moderate correlation of SLJ (r = .720, r = .514) were shown on L5 and Ankle. On land environment, moderate to high correlation are shown on C7 and L5 (r=0.44-0.90). The only SLJ were shown a moderate correlation on Ankle (r=0.641). During five-times continuous CMJ, moderate to high correlations were shown on C7 and L5 in water and on land (r = 0.67~0.74). In contrast, there was no correlation between total ACC and GRF on the Ankle.
CONCLUSION: The correlation between ACC and GRF were moderate to high on C7. It is feasible to detect the jumping force whether single jump or continuous jump in water or on land.

FLOW CHARACTERISTICS AROUND FOREARM DURING FRONT CRAWL SWIMMING.

SHIMOJO, H., EBIHARA, R., GONJO, T., SENGOKU, Y., TAKAGI, H.

NIIGATA UNIVERSITY OF HEALTH AND WALFARE

INTRODUCTION:It has been considered that propelling swimmer push the water by the forearm and gain the reactive force during front crawl swimming. In this study, to describe the phenomenon of human swimming, we visualized the flow structure around swimmer's forearm during front crawl swimming.
METHODS: One national level male swimmer performed front crawl swimming at circular water flume. We used both motion capture to record the swimmer's 3D motion and stereo particle image velocimetry (stereo PIV) to visualize flow pattern around the forearm during swimming. The swimmer swam while 15 s at each trial under 1.2 m/s flow velocity condition, and repeated the trial 21 times at different space in flume.
RESULTS: Turbulence flow, i.e. leading edge vortex, was observed around the tip of the finger at first of in-sweep stroke, which causes a pressure difference between the dorsal and palm sides of the hand (1). In addition, long axial flow streamed directly from upper arm to forearm in the same timing. Both flows engulfed around the palm side of the wrist, which created the jet flow gradually around the fore-

arm. After that, the direction of hand was changed from in-sweep to out-sweep and the swimmer accelerated forward soon. The vortex behavior might have the role for thrusting force during front crawl swimming.
CONCLUSION: During front crawl swimming, swimmer created leading edge vortex and axial flow around forearm at in-sweep motion, which might have the role to strengthen thrust force generation.

INFLUENCE OF FOOT PROGRESSION ANGLE ON KNEE ADDUCTION AND FLEXION MOMENT DURING STAIR CLIMBING IN HEALTHY INDIVIDUALS

TSUKAGOSHI, R., GOTO, M., SENOU, H., HONDA, R.

HYOGO UNIVERSITY OF HEALTH SCIENCES

INTRODUCTION:It has been confirmed that toe-in and toe-out modifications reduce the knee joint load during walking (1). Only a few reports, however, have focused on stair climbing, which requires a higher load than walking (2). Patients with knee osteoarthritis have more pain and difficulty with stair climbing than with walking and sit-to-stand movements, suggesting that a reduced mechanical load on the knee joint during stair climbing might contribute to improving performance and quality of life. The purpose of this study was to investigate the effect of foot progression angle on knee joint load and related variables during stair climbing.
METHODS: Twenty healthy young adults performed a stair climbing task at predefined speed (90 steps/min) with normal foot progression angle (normal), toe-out (15° > normal) and toe-in (15° < normal). Three-dimensional motion analysis was performed. The ground reaction force with three components, center of pressure positions, and sagittal and frontal plane hip and knee joint kinematic and kinetic variables were recorded during stair climbing. The stairs consisted of two steps placed on a force plate. The height of the first and second steps were 16.5 cm and 33.0 cm, respectively. The treads of the steps were 40 cm. Ground reaction force data from the first step were used for kinematic and kinetic analyses.
RESULTS: The first and second peak medial ground reaction forces were smallest to greatest (and significantly different) in the order of toe-in, normal, and toe-out. The center of pressure at the first peak of the knee adduction moment of the toe-out condition was significantly more lateral than the normal and toe-in conditions. During the stance phase, peak knee adduction angles were smallest to greatest (and significantly different) in the order of toe-in, normal, and toe-out. The peak external knee flexion moment of the toe-in condition was significantly decreased compared with the normal and toe-out conditions. The first peak knee adduction moment during the toe-in condition was significantly decreased by about 21% compared with the normal condition and by about 33% compared with the toe-out condition, whereas that of the toe-out condition was significantly increased by about 21% compared with the normal condition. The knee adduction angular impulse during the toe-in condition showed significant reduction compared with the toe-out condition.
CONCLUSION: The toe-in condition successfully reduced the first peak knee adduction moment compared with the normal and toe-out conditions. In addition, the toe-in condition reduced the peak knee flexion moment, which is related to the contact force in the medial compartment of the knee joint. These results indicate that toe-in is the most advantageous strategy for reducing the knee joint load during stair climbing, especially in the medial compartment of the knee joint.

THE EFFECTS OF PILATES MAT EXERCISE TRAINING ON THE FUNCTIONAL MOVEMENT SCREEN AND POSTURAL STABILITY IN YOUNG FEMALE ATHLETES

LEE, A.J.Y., WANG, Y.T., ZAHALKA, F., ERTAN, H., AKILA, S.

NATIONAL TSING HUA UNIVERSITY

INTRODUCTION:Pilates mat exercise is a type of training that can strengthen the core muscles and movement control. The purpose of this study was to evaluate the effects of regular Pilates mat exercise training (PMT) on the functional movement screen (FMS) and postural stability (PS) in healthy young female athletes.
METHODS: 34 healthy collegiate basketball athletes volunteered and assigned randomly to the experimental or control groups in equally. The experimental group underwent PMT exercises twice a week for eight weeks, but the control group did equal time of warm-up and stretch exercise only. The PMT totally had fifty minutes training: a 5-mins warm-up and stretch exercise, 40-mins main exercise, and 5-mins cool-down exercise. The score of FMS were evaluated by one certified professional experts. The PS was evaluated by the 8-direction limits of stability (LOS) test using the Biodex Balance System. Repeated measures analyses of variance (ANOVAs) were conducted to determine if any difference existed between groups and time of testing in any of these parameters.
RESULTS: The FMS and LOS performances in the PMT group were significantly improved after training, including the in-line lunge, active straight leg raise, trunk stability push-up, and rotary stability of the FMS, and the directions of forward, left, right, forward-left, and forward-right of the LOS.
CONCLUSION: It is concluded that regular PMT can improve the performance of FMS and dynamic postural stability in healthy young athletes.

THE DIFFERENCES BETWEEN ON-ICE AND OFF-ICE AGILITY DEVELOPMENT IN HIGH SCHOOL ICE-HOCKEY PLAYERS

STASTNY P., NOVAK, D.

CHARLES UNIVERSITY, FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION:The agility plays crucial role in ice-hockey training where it might be developed directly on-ice or by additive off-ice training. Since the effectiveness of on-ice and off-ice training on players agility has not been described the purpose of this research is to compare additive four weeks on-ice and off-ice agility training on the skating performance. Moreover, the description of the methods, which should lead to ice hockey agility development, are usually based on empiric rather than evidence based data.
METHODS: Fourteen ice hockey players (age 14.8 ± 0.45, body mass 61 ± 10,43; height 168,93 ± 9,72; training experience 9,07 ± 0,75) trained agility on-ice for 4 week and off-ice for 4 weeks in crossover design, when they were tested before the additive agility program after first month and after finishing both training programs. The players were randomly assigned into one group performing on-ice training protocol as first (Ice1) followed by off-ice agility training and group performing on-ice training as second (Ice2) after of-ice agility intervention. The test battery included, straight sprint to 6.1m and 35m, S-Corner test, Break test, weave agility with puck and reactive agility test. Changes in selected parameters for two groups (Ice1 vs Ice2) and ratio of the changes were analyzed with a spreadsheet for

analysis of parallel-groups controlled trials, changes in selected parameters according type training for all subjects together were analyzed using a spreadsheet for post-only cross over trial, suitable also for repeated measurements of subjects in one group (Hopkins 2017). Effects were interpreted using magnitude-based inferences (MBI) (Hopkins, Marshall et al. 2009).
RESULTS: The magnitude based inference analyses showed the effect of agility training in both groups in the weave agility (Ice1 improved 2.9±2.8%, Ice2 improved 3.1±2.5%) and reactive agility (Ice1improoved 3.1 ±2.5%, Ice2 improved 1.7±2.1%), where Ice1 group resulted in likely positive change and Ice2 group in possible change positive change. The comparison of training effect on ice resulted in higher positive change (by 1.0 ± 5.1%) than the training off-ice in reaction agility.
CONCLUSION: Both training interventions resulted in agility improvement, where on-ice training is probably more effective in term of specific agility. However, there is evidence that off-ice agility might support the on-ice agility in high school players. Therefore, we recommend the interchange of on-ice and off-ice additive agility training in during the ice hockey season.

ELUCIDATING THE TOSS-BATTING MOVEMENT IN BASEBALL WHEN HITTING TOSSED BALLS OF DIFFERENT SPEEDS

TAGO, T.

TOKUSHIMA BUNRI UNIVERSITY

INTRODUCTION:Batting movements in response to baseballs pitched at different velocities have been studied from the perspective of ground reaction forces and timing of the stepping leg, but no study has addressed the question of a rotation of the body trunk, which is fundamental to body movement. Recent increase in the use of change-up pitches suggests that the identification of movements used to adapt to different ball velocities would provide useful information for coaches. The purpose of this study was to elucidate the differences in the toss-batting movement in baseball, with the focus on the rotation of the body trunk, when the speed of the ball is varied.
METHODS: The subjects were 10 experienced university baseball team members selected on the basis of instructor evaluations. All batting motions used in the present study were those normally used in the competitive field. The order of the trials for each toss up ball were determined randomly. For each trial, they were asked to take a moment to formulate a 5-point assessment (5, very good; 3, normal; 1, very bad) that comprehensively took into account the intensity and direction of the ball. The trials that received the highest assessment scores were subject to further analysis. An imaging area 3.0 m in the right-left direction (X-axis), 4.0 m in the direction of the centre field (Y-axis), and 2.5 m high (Z-axis) was established, and 2 high-speed cameras (HSV-500C3, NAC Inc., Tokyo, Japan) were used for front and side imaging of the trials. The experimental trials were videotaped at a frame rate of 250 Hz and an exposure time of 1/1,000 s. Statistical significance level set at $P < 0.05$. Statistical analysis were performed using the SPSS Statistics 15.0 (SPSS Inc., Chicago, IL).
RESULTS: When the ball was tossed slowly, the rotation of the hips in the second phase started to rotate towards the direction of the ball, stopped rotating for a moment, did not re-start rotating again, and showed no differences in movement according to differences in the toss speed. The rotation of the shoulders showed no differences in movement according to the difference in toss speed either.
CONCLUSION: In terms of the movement made in response to balls tossed at different speeds, parameters such as the rotation angle of the shoulders and hips, which are thought to directly influence the ball that is hit, showed no changes until near the heel contact (second phase). What is more, the fast toss and the slow toss produced similar patterns of changes. This suggested that the batter was trying to maintain a posture that would allow him to adjust the timing easier, by controlling the excessive opening of the body from the toe off to the heel contact of the step leg, primarily.

CHARACTERISTICS OF STRENGTH AND ELASTICITY ON JUMP PERFORMANCE IN COLLEGIATE JUDO PLAYERS.

KOYAMA, T.

COLLEGE OF HUMANITIES AND SCIENCES, NIHON UNIVERSITY

INTRODUCTION:A strength training such as deadlift, squat or bench press is one of the common weight training programs in judo. However, in judo players, there are physical variations that some have excellent strength, others have excellent flexibility or elasticity. Although it is important to plan a strength training that matches the physical characteristics of each player, it seems that a strength training program does not necessarily reflect individual muscle characteristics such as speed-strength or elasticity in judo. These physical properties are indirectly assessed by several jump test. Thus, the purpose of this study was to determine the characteristics of strength and elasticity on jump performance in judo players.
METHODS: Thirty-eight Japanese collegiate judo players participated in this study. The mean (SD) age, height and weight were 20.0 (1.1) ys, 176.1 (5.5) cm and 87.0 (18.2) kg. The players were divided into lightweight class (12 players), middleweight class (17 players) and heavyweight class (9 players). Three jump tests (squat jump; SJ, counter movement jump; CMJ and rebound jump; RJ) were measured by using multi-jump tester 2 (DKH inc., Japan). After some practice, SJ and CMJ were measured at 1 rep, 2 trials, and RJ was measured at 5 reps, 1 trials. SJ maximum height (cm), CMJ maximum height (cm), RJ mean height (cm) and RJ index were recorded into a spreadsheet. percentage difference between SJ and CMJ (% difference) was calculated as (CMJ-SJ)/CMJ. Multiple comparison was used to compare each parameter between weight classes. Pearson's correlation analysis was conducted between parameters for all players. In order to categorize the characteristics of strength and elasticity of each player, the % difference and RJ index was divided equally into three groups of high, moderate and low.
RESULTS: Heavyweight class was significantly lower than lightweight and middleweight class in SJ, CMJ, RJ height and RJ index. There was a significant positive correlation between SJ, CMJ, RJ height and RJ index. In the % difference, there was only correlated with SJ (r=-0.360). All players were categorized into 9 groups (from high % difference/high RJ index to low % difference/low RJ index).
CONCLUSION: In jump performance, heavyweight class was inferior to lightweight and middleweight class although heavyweight class is physically large body build. The % difference is a possible measure for judging whether the height of the vertical jump depends on muscular strength or elasticity. In other words, low % difference means strength dominance jump whereas high % difference means elastic recoil dominance jump. Also, high RJ index means that player has excellent elasticity. Finally, the results of this study suggest that by using % difference and RJ index, judo players can be categorized based on the strength and elasticity properties, which can help to plan individual training programs according to each subtype.

THE DEVELOPMENT OF A REACTIVE BALANCE TEST

VERSCHUEREN, J.1, TASSIGNON, B.1, PLUYM, B.1, VAN CUTSEM, J.1, VERHAGEN, E.2, MEEUSEN, R.1

VRIJE UNIVERSITEIT BRUSSEL <1>; VRIJE UNIVERSITEIT AMSTERDAM <2>

INTRODUCTION:Balance tests are commonly used in clinical practice with applicability in injury prevention and return to sport decisions. While most sports injuries occur in a changing environment where reacting to a non-planned stimulus is of great importance, these balance tests only evaluate pre-planned movements without taking these dynamics environmental aspects into account. Glasgow et al. (2013) illustrated that reacting to a non-planned stimulus is of great importance in sports. They state that the key driver for effective sporting performance and injury prevention is the athlete's ability to adapt his or her responses under a comprehensive variety of conditions (1). Therefore, the goal of this paper is to develop a clinician-friendly test that respects these contextual interactions and to describe the test protocol of an adapted y-balance test that includes environmental perception and decision-making.
METHODS: The methodology of Kazman et al (2016) (2) is used to systematically describe the development of the reactive balance test (RBT). Within the theoretical construct of balance and adaptability, balance errors are selected as outcomes measures for balance ability and visuomotor reaction time and accuracy are selected as outcome measures for adaptability. A reactive balance task is developed and described using the Y-balance test for the balance component, while the FitLight training system© was chosen for the environmental perception and decision-making component of the test.
RESULTS: This paper describes the test protocol of a reactive balance test as an adapted Y-balance test. Instructions and recommendations for standardized YBT protocol, with corresponding rationale for every recommendation are adopted from Plisky and colleagues (2009) (3) and applied to the RBT. To induce cognitive load, the VMT task was developed using 12 randomised stimuli along each axis of the YBT to reach a test duration of 90 to 120 seconds. Within the visuomotor task, colours are fixed to a corresponding axis with both the order of the visual stimuli as the interstimulus time being randomised to integrate environmental perception and decision-making. The reach distance of the reactive balance test is set to 80% of the maximal reach distance on each of the Y-balance axes to adequately stress balance and induce balance errors, while still enabling the subject to timely continue the test sequence.
CONCLUSION: This test protocol describes a reactive balance test that adds environmental perception, decision-making and variable motor responses as additional dynamic components to the construct of balance. The reactive balance test is a functional test that allows clinicians to score balance ability and athlete adaptability easily.

MECHANICAL AND NEUROMUSCULAR PROPERTIES OF SELECTED LOWER LIMB MUSCLES IN MALE TRACK AND FIELD ATHLETES.

HIRATSUKA, K.1, MIYAZAKI, D.1, SIMUNIC, B.2, DJORDJEVIC, S.2, TSUNODA, N.1

1: KOKUSHIKAN UNIVERSITY , 2: UNIVERSITY OF PRIMORSKA

INTRODUCTION:Tensiomyography method as non-invasive technique was developed to evaluate the mechanical and neuromuscular properties of selective skeletal muscle (1). The tensiomyography mechanical and neuromuscular properties of have been used to investigate the fiber composition in skeletal muscle. However, mechanical and neuromuscular properties of sprinters and long distance runner in track and field athletes by tensiomyography is not so reported. Therefore, in this study, it is to clarify the mechanical and neuromuscular properties of lower limb muscles in sprinters, middle distance runners, long distance runners and throwers.
METHODS: One hundred nineteen male collegiate athletes of sprinters (SP; n=29, 20.2±1.9yrs), middle distance runners (MDR; n=19, 20.5±1.2yrs), long distance runners (LDR; n=33, 19.9±1.4yrs) and throwers (TH; n=38, 20.4±1.9yrs). The mechanical and neuromuscular properties of rectus femoris (RF), vastus medialis (VM), vastus lateralis (VL) and biceps femoris (BF) in thigh, and tibialis anterior (TA) and gastrocnemius medialis (GM) in leg were assessed by tensiomyography (TMG method). Mechanical and neuromuscular properties of delay time (Td), contraction time (Tc) and maximal displacement of the muscle belly (Dm) were analyzed in each groups.
RESULTS: Td of RF and BF in SP and TH were significant shorter reaction times than MDR and LDR. And Td of RF in MDR and LDR were showed same values. Td of VL, VM and TA were not significantly different in among the groups. Tc of RF and VM in MDR and LDR were significantly longer contraction time than SP and TH. And Tc of BF in LMD was obtained longer contraction time among the groups. Tc of TA and GM were not significantly different in among the groups. Dm of RF in TH was significantly lower value than SP, MLD and LMD. And also, same tendency was observed for VM, BF and TA. Dm of VL and GM were not significantly different in among the groups.
CONCLUSION: In this study, neuromuscular properties for rectus femoris and biceps femoris muscles in sprinters and throwers were significantly differed compare to the middle distance runners and long distance runners. And mechanical properties for rectus femoris, vastus medialis, biceps femoris and tibialis anterior muscles in throwers were significantly lower compared to the sprinters, middle distance runners and long distance runners. From these results, it was considered that neuromuscular and mechanical on lower limb muscles measured by TMG method may reflect to the muscle fiber composition.

KINEMATICS AND MUSCLEACTIVITY OF THE LOWER LIMB DURING ONE LEG STAND ON DIFFERENT SURFACES (PILOT STUDY)

MAYER, P., VASS, L., VÁCZI, M.

UNIVERSITY OF PÉCS, FACULTY OF SCIENCES, INSITUTE OF SPORT SCIENCES AND PHYSICAL EDUCATION

INTRODUCTION:TOGU Jumper is a very popular piece of equipment which is routinely used in many fitness facilities, physical therapy, and athletic training rooms for balance training and for improving of proprioception. TOGU Jumper is a balance trainer that combines a solid plastic base with an inflatable bladder and we can use both sides of the device. The purpose of this study is to determine which side of the TOGU would generate a greater amount of electric muscle activity and a difference in the kinematic of the leg.
METHODS: Participants were healthy, recreationally, physically active, collegeaged females. Each subject performed 2 single-leg barefoot stance trials at first on a flat rigid surface and then on each side of the TOGU. We measured the electromyogfraphic activity of four lower

(tibialis anterior, gastrocnemius medialis, peroneus longus, soleus), three upper leg (vastus medialis, vastus lateralis, biceps femoris) and one hip muscle (gluteus medius). Noraxon MyoMotion(USA) motion analysis system was employed to analyse kinematic variables. The average data which were measured on the flat rigid surface served as baseline measurement (control condition).
RESULTS: According to the results we can say that the muscle activity of the lower leg muscles are greater than the EMG activity of the upper leg muscles during an unipedal stance and we found no significant differences in EMG data for any muscle between conditions ($p > 0.54$).
CONCLUSION: Because of the low number of participiants we found no significant difference between the data, so it is necessary to increase the number of subjects.

VARIABLE, BUT NOT FREE-WEIGHT, LOADED COUNTERMOVEMENT JUMP EXERCISE POTENTIATES JUMP PERFORMANCE FOLLOWING A COMPREHENSIVE TASK-SPECIFIC WARM-UP

MINA, M.A.1, BLAZEVICH, A.J.2, TSATALAS, T.3, GILES, D.1, KALOTYHOS, S.3, GIAKAS, G.3, HOOTON, A.1, KAY, A.D.4
1: UOD , 2: ECU , 3: UOT , 4: UON

INTRODUCTION:The inclusion of maximal or sub-maximal muscle actions using elastic bands (EB) in combination with free-weight (FW) resistance can manipulate the loading characteristics of these actions. When performed during a warm-up, short-term increases in force production to further augment performance can occur, a state often referred to as post-activation potentiation. However, these improvements are often reported after limited or no warm-up was imposed. The aim of the present study was to examine the influence of EB resistance following a comprehensive warm-up on subsequent countermovement jump (CMJ) performance.
METHODS: Fifteen active men (age = 21.7 ± 1.1 y, height = 1.8 ± 0.1 m, mass = 77.6 ± 2.6 kg) volunteered for the study. On two separate occasions, participants performed a comprehensive warm-up of 5 min cycling, 10 continuous unloaded squats, 5 continuous CMJs at ~70% of maximum, then maximal jumps were performed every 30 s until 3 jumps were within 3% of maximum jump height. Participants then performed 5 repetitions of either EB- or FW-loaded CMJs at 50% 1-RM (35% of load generated from elastic resistance during EB). CMJs were then performed 30 s, 4 min, 8 min, and 12 min later. During CMJs, motion analysis and two force platforms recorded kinematic and kinetic data, with vastus lateralis, vastus medialis, gluteus maximus, and gastrocnemius medialis electromyograms (EMG) recorded simultaneously.
RESULTS: Significant increases in CMJ height (4.6-8.0%), net impulse (2.1-3.7%), peak power (3.9-5.0%), and peak eccentric kinetic energy (10.0-11.5%) were observed at 30 s and 4 min after EB; no changes were found at 8 min and 12 min. No difference in knee angular velocity, knee flexion angle, rate of force development or EMG activity were found at any time point. No changes were observed in FW.
CONCLUSION: The lack of change in jump performance in FW suggests that the comprehensive warm-up potentiated the neuromuscular system such that subsequent FW contractions provide no further improvement in CMJ performance. Nonetheless, CMJ performance was significantly increased following EB at 30 s and 4 min, with increases in force production consistent with the changes in CMJ height. A number of mechanisms relating to stretch-shorten cycle efficiency may have contributed to the increase in CMJ height, including a more rapid muscle stretch resulting from force potentiation and greater elastic energy storage in the muscle. Regardless of the mechanism, elastic band use may enhance athletic performance even when a full warm-up is completed.

CHANGES OF KINEMATICS AND GROUND REACTION FORCE WITH INCREASE IN RUNNING VELOCITY IN MIDDLE-AGED RECREATIONAL MARATHON RUNNERS

TOKUI, M.
KYUSHU KYORITSU UNIVERSITY

INTRODUCTION:During running, the runner exerts a force on the ground to propel the body and increases the velocity by increasing step length and frequency. The purpose of this study was to investigate the change of kinematics and ground reaction force with increase in running velocity in recreational middle-aged marathon runners.
METHODS: Thirteen recreational marathon runners (Five men; 50.8±5.2 yr, 168.8±10.7cm, 59.2±13.Kg, Eight women; 49.3±8.4yr, 160.6±7.5cm, 52.8±6.6kg) voluntarily participated in this study.
The runners ran at a running pace of six to ten stages chosen by oneself from the following running paces (every 30" from 7'00"/km to 2'30"/km) with several minutes interval on experimental running lane setting in indoor all weather direct track, and were leading by lighting pacemakers for adjusting the exact running pace.
Measurement methods of kinematics and ground reaction force in measurement section in running lane were as follows; three dimensional data of twenty-eight landing points of human body were obtained by motion capture system (MAC3D, Motion Analysis, USA, 200H) and ground reaction force was measured by four force platform (9287B, Kistler Inst., Switzerland, 1000Hz).
Running velocity, step length and step frequency were calculated from three dimensional data. Direction of ground reaction force defined as breaking (negative horizontal; Y), propulsive (positive horizontal; Y), and vertical (Z). Impulse was calculated by integrating each ground reaction force (Kine Analyzer, Kissei Comtec, Japan).
RESULTS: The peak value of ground reaction forces (breaking, propulsive, and vertical) increased with increase in running velocity in all runners. On the other hand, the ground contact time in one step decreased with increase in running velocity in all runners.
Consequently, the change of the impulse with increase in running velocity was different every force direction. Namely, breaking impulse increased, propulsive impulse did not change, and vertical impulse slightly decreased.
The step length and the step frequency in each runner was linearly increased with increase in running velocity. The function of the step length for the running velocity ($y=0.268x+0.2297$, $r=0.97$) showed larger inclination and higher correlation compared with that of the step frequency ($y=0.1475x+2.4648$, $r=0.62$).
CONCLUSION: The running kinematics and the ground reaction force with increase in running velocity in recreational middle-aged marathon runner were investigated. The ground reaction force of three directions increased with increase in running velocity, but the impulses showed different change depending on the direction. The step length predicted the running velocity than the step frequency.

EFFECT OF THREE FOOTSTEP EXERCISE ON GAIT FUNCTION AND SENIOR FITNESS TEST IN ELDERLY FEMALE

PIL-HA, H., TAE-DONG, K., SEONG-DEOK, Y., JA-MIN, K., GI-DUCK, P.

KYUNGPOOK NATIONAL UNIVERSITY, KEIMYUNG COLLEGE UNIVERSITY

INTRODUCTION:Modern society is increasing the elderly population with the development of medicine and technology. Factors that cause the fall in older people include muscle weakness, increased variability in Gait, and postural instability. In particular, the importance of regular physical activities for older women is emphasized more because they have fewer physical activities such as walking and muscle exercise than men. Three footstep Korean dance moves similar to the order of foot contact in normal walking steps, and the action that emphasizes movement of ankles is repeated. The purpose of the study is to identify the impact of three footstep on the Gait and Senior Fitness test of Elderly Female, and to provide specific data for the development of exercise programs for older women.
METHODS: The study selected 15 exercise groups and 15 control groups for aged 75 and older women living in the S city of Gyeongsangbuk-do and W-gun, Jeollanam-do, and the criteria for selecting participants are those who do not participate in continuous exercise programs for the past year. The groups were tested for walking functions, foot pressure, and senior fitness test of the elderly in advance, and post-measurement measures were performed after a 10-week three-step walk. The exercise program was conducted for 10 weeks, 2 time, for 50 minutes.
RESULTS: The result obtain. First, in the gait function, cadence and gait speed showed significant increase in the experimental group as the temporal gait parameters(P<.01). second, 2.44m walking, sit up and sit down on the chair and sit on a chair reach out to a significant difference(P<.01).
CONCLUSION: Through this study, Three footstep exercises will bring positive changes to elderly females gait functions and senior fitness test and provide detailed data on exercise programs that will help them become healthy and successful in their old age.

RELATIVE POWER AND ELECTROMYOGRAPHIC ACTIVITY IN UNIVERSITY VOLLEYBALL PLAYERS FOR COUNTERMOVEMENT AND ABALAKOV JUMPS.

AEDO-MUÑOZ, E.1,2, ROJAS, C.5, TAMAYO, V.2, BRITO, C.3, MIARKA, B.3,4, HERNÁNDEZ, C.5, PARDO, C.2, ZAPATA, C.2 ARGOTHY-BUCHELI, R.6

1 UNIVERSIDAD DE SANTIAGO DE CHILE; 2 UNIVERSIDAD SANTO TOMÁS; 3 UNIVERSITY FEDERAL OF JUIZ DE FORA; 4 FEDERAL UNIVERSITY OF RIO DE JANEIRO; 5 UMCE; 6 ESCUELA MILITAR JOSÉ MARIA CORDOVA

INTRODUCTION:Many investigations have pointed to the development of vertical jump performance (Viitasalo & Bosco, 1982) (Chu & Myer, 2013). Contractile muscle activity can be assessed by a technique called electromyography (EMG), which records the electrical activity that manifests itself in the muscle when activated by the central nervous system to perform a contraction. The EMG provides information about muscle activation time and an estimate of the strength contributed by the muscle used (Enoka & Duchateau, 2016). For measurements that involve dynamic movements, such as jumps or runs, surface electromyography (EMGs) is used, which is captured by means of electrodes located in the belly of the muscle group to be measured (Hermens, Merletti, & Freriks, 1996). The electromyographic magnitude is the quantity or intensity of muscular electrical activity, which is related to the root mean square (RMS) of the raw signal, describing technically the power of the signal.
METHODS: 24 university volleyball players were separated into two groups same assigned by the division. Group 1 (G1) is composed of volleyball players from the 1st university division and group 2 (G2), is composed of volleyball players from the 2nd university division, its were simultaneous measurements of power and EMGs. For power were used a 2D recording system, tracking the larger trochanter through a camera that captures at 250 fps. This recording was subjected to a measurement of software (Tracker®), to obtain the absolute power values. The EMGs were performed Delsys Trigno® electromyograph in the muscles GM, VM, VL and GASLAT
RESULTS: The relative power in CMJ, G1 (28.55±3.47 Watts/kg) and G2 (28.46±4.07 Watts/Kg), while the relative power in ABK G1 (33.10±4.02 Watts/Kg) and G2 (33.56±5.15 Watts/Kg). These small differences between the groups in different jumps did not show significant differences between the groups in a jump CMJ (p>0.05) and ABK (p>0.05). the electromyographic activity of the GM (57.5±13.3 uV) and VM (171.5±59.7 uV) muscles, the G1 athletes showed less activity than the G2 athletes in GM (62.4±33.2 uV) and MV (189.7±120.9 uV), where none of them presents statistically significant differences (p> 0.05). However, the electromyographic activity in VL (203.1±77.2 uV) and GASLAT (253.4±25.21 uV) of G1, compared to the same muscles of G2, presented statistically greater differences (p <0.05). In both groups for the ABK jump where no differences were found in the values of G1 in GM (59.6±18.4 uV), VM (203.2±82.2 uV) and VL (204.3±81 uV)), with the G2 values in the same muscles GM (63±37.5 uV), VM (191.9±137.9 uV) and VL (172.3±65.1 uV). However, in the contrast of the GASLAT between G1 and G2 statistically significant differences were found (p <0.01) in an ABK jump.
CONCLUSION: Significant differences in RMS of the VL and GASLAT (p<0.05) in a CMJ between G1 v/s G2 and GASLAT (p=0.001) in ABK between G1 v/s G2 were presented, for the relative potency no significant differences were presented, CMJ and ABK (p>0.05).

STABILITY OF THE BENCH PRESS MOVEMENT IN PARA-POWER LIFTING ATHLETES

SUGAJIMA, Y., ISHIDA, N., KATO, T., HONDA, A., TAKAHASHI, A., YAMAMOTO, H.

ASAHI UNIVERSITY

INTRODUCTION:In the para-power lifting (PPL) competition, the stability of the bench press movement greatly affects the competitive performance, and establishing a stable form is an important factor for its improvement. It is very important to examine what constitutes a stable form to improve grades and what factors affect the form. However, there are few studies on the stability of the bench press movement and there are no reports targeting PPL athletes. Previously, we observed that bilateral differences in movement and pressure center (COP) of the upper limbs occur in the bench press movement in healthy power lifting (PL) athletes. Therefore, the purpose of this study was to examine the factors of the left and right differences in movement and COP of the upper limbs during bench press by analyzing dynamic muscle strength around the shoulder.
METHODS: Three men, including two PPL athletes (1 right thigh cut, 1 spinal cord injury) and one healthy power lifting (PL) athlete participated in this study. Everyone was right-handed and performed five consecutive bench press movements with 70% weight (W) and 50% W of their bench press 1 RM. Markers were affixed to 18 points on the left and right sides of the shaft and upper body, and bench press movements were measured using nine infrared cameras (Vantage / Vero, VICON) and analyzed three-dimensionally. Simultaneously, pressure center (COP) during the bench press was measured using a force plate (9281 E, KITLER). Isokinetic muscle strength around the shoulder was measured using a dynamometer (System-4, Biodex).

RESULTS: We focused on the differences between the left, right, top, and bottom positions of the bench press movement. During the bench press, the COP was displaced to the left for all athletes. The displacement was greater at 70% W than at 50% W and was greater at the top than at the bottom. The heights of the shoulder, elbow, and shaft were lower on the left at the top for all the players, and the differences tended to increase with higher positions from the shoulder. The muscle strength of the left shoulder was lower than the right at 60 degrees per second.
CONCLUSION: In the bench press movement, it was confirmed that there is a difference in the left and right movements. It was thought that this was attributed to the difference in muscular strength of the shoulders throughout the movement, causing the displacement of the COP to the left. Moreover, as players have a history of injuries around the shoulders; it seems that the background of the left and right differences may be related to shoulder injuries.

RELATIONSHIP BETWEEN DYNAMIC BALANCE AND CHANGE OF DIRECTION PERFORMANCE IN FEMALE LACROSSE ATHLETES

TE, T.J.1, LIM, J.H.1, CHAN, L.1, HO, T.1, LIN, R.1, HO, S.H., NASSIS, G.P.2

1. SPORTSLINE ASIA 2. DEPARTMENT OF SPORTS SCIENCES, CITY UNITY COLLEGE, ATHENS, GREECE

INTRODUCTION:The ability to change direction is an integral component of field-based sport. However, multi-directional changes are also a key component associated with noncontact anterior cruciate ligament injuries (1). Therefore, understanding the biomechanical risk factors and mechanical determinants of faster change of direction (COD) performance are of great interest. The Y Balance Test (YBT) is a screen test of dynamic balance requiring stance leg balance while the contralateral leg reaches in anterior (ANT), posteromedial (PM), and posterolateral (PL) directions, and has been proposed as a screen for injury risk (2). The Pro Agility Test (5-10-5) is an assessment of agility and is designed to minimize the influence of individual differences in sprinting velocities while accentuating the effect of acceleration immediately before,during, and after the COD (3). This study aimed to investigate the relationship between dynamic balance and COD performance in female athletes.
METHODS: 19 female lacrosse athletes (age=17.6±1.7yrs, training experience= 1.7±1.1yrs) performed the Y Balance Test and the Pro Agility Test (5-10-5). For the YBT, the athletes performed contralateral leg reaches in the 3 directions and the maximal reach distance of three trials for both legs was recorded for analysis (2). For the Pro Agility Test, three marker cones are placed along a line 5m apart. The athlete turns and runs 5m to the right side and touches the line, runs 10m to his left and touches the other line, then finally turns and finishes by running back through the start/finish line. The athletes completed three trials each; one practice and two main trials with at least 4 minutes of recovery between each trial (3). The best time out of two trials was picked for analysis.
RESULTS: The total composite score (CS) ranged from 133% to 172% and the 5-10-5 performance from 5.06 secs to 5.79 secs. There was no correlation between the CS (R^2=.004; p=.80), left leg CS (R^2=.001; p=.90), right leg CS (R^2=.008; p=.73), left anterior reach (R^2=.03; p=.47), right anterior reach (R^2=.05; p=.37) and change of direction performance.
CONCLUSION: These results indicate that the composite score reported by the YBT and the COD performance time in the 5-10-5 test do not share common traits. YBT is a standing balance test whereas 5-10-5 requires quick changes in body posture and hence body balance control while moving at high speeds.

SELECTED SHOULDER MUSCLES ACTIVATION DURING THE PERFORMANCES OF MEDICINE BALL CHEST PRESS EXERCISE IN THREE DIFFERENT POSITIONS

ABU ALIM, M.

YARMOUK UNIVERSITY

INTRODUCTION:Shoulder pain and injuries have been linked to muscular and alignment dysfunctions (1). Sedentary life and work environments prevent the engagement of the body chain during task excursion which leads to muscle weakness and activation patterns dysfunction, causing instability and increased risks of injuries especially in women (2). Identifying the impact of exercise performance-related muscular activation in a different position may contribute to the description of appropriate training strategies to promote stability and enhance the function of the shoulder.
METHODS: Fifteen female participants aged (23±3 years) weighted (66.7±8.4 Kg) performed the chest-press exercise using a medicine ball (15 lbs ˜ 6.8 kg) (ChPwMb) in three different positions (seated, supine and standing). Surface EMG data were collected from the following muscles during the performance: Upper Trapezius UT, Lower Trapezius LT, Latissimus Dorsi LD, Posterior Deltoid PD, Anterior Deltoid AD , Serratus Anterior SA. In each position, subjects performed three trails, with a constant velocity timed by a stopwatch. All EMG data reported as a percentage of RMS mean values obtained in maximal voluntary contractions that lasted for 5s of each selected muscle of participants dominated side. ChPwMb exercise was divided into two phases forward phase (push the ball away from the body) and the recovery phase (get the ball back to chest). Repeated measures ANOVA was performed to compare RMS normalized values among ChPwMb exercise positions and phases.
RESULTS: Overall the results indicated significant differences in the activation of the selected shoulder muscles between the standing and the supine position and between the seated and supine position during the performance of the ChPwMb exercise. Whereas, no significant differences were shown in the activation of the selected muscles between the seated and the standing position of the ChPwMb exercise performance. During the chest press performance in the standing position the LD (38.7% RMS), PD (45.8% RMS), AD (37.6%RMS) muscle were the most active compared to the other muscles and were more active during the second phase. Whereas performing the ChPwMb exercise in the seated position the PD (49.5% RMS), AD (46.1 %RMS) were the most active and had higher activation in the second phase of the exercise. Performing the ChPwMb exercise in the supine position muscles had the lowest activity levels compared with the two previous positions, and the most active muscle was the anterior deltoid (35.3% RMS).
CONCLUSION: The performed quantification of the muscle activity could help to determine the changes in muscle activity around the shoulder region due to changing in body position while performing the chest press exercise with a medicine ball. Also, the results could help in promoting an environment-friendly exercise intensity for shoulder stability and enhance function.

ACCURACY DETECTION OF WALKING PARAMETERS ON SMART SHOES ACCORDING TO VARIOUS SPEEDS

ROH, J.

KITECH

INTRODUCTION:Smart shoes could continuously acquire big data such as walking or running pattern and habit as well as the walking time and cycle information. Smart shoes are equipped with a number of pressure sensors in the insole or outsole. While many pressure sensors can detect more precise gait patterns, they can increase the cost of commercialization and weaken your purchasing power. This study was undertaken to define the minimum quantity and anatomical position of sensors in the smart shoes according to various speeds.
METHODS: The 10 subjects (29.6±4.5 years, 175.3±4.6cm, 74.8±5.2kg) participated in this investigation and walked at four different constant speed (3, 5, 7 and 9 kph) on a motorized treadmill for more than 30 Sec. Each subject was simultaneously wearing an insole type foot pressure monitoring system (Pedar® system, Novel GmbH, Germany) in a smart shoes (IOFIT, Salted Venture, Korea) equipped with four pressure sensors in the outsole. The signals of the insole type foot pressure monitoring system were analyzed to compare the accuracy (%) of the smart shoes for the gait cycle time (GCT) and the ratio of stance/swing phase (RssP) respectively. The four sensor positions were toe (between 1st & 2nd pharange), 1st metatarsal head (MH), 4th metatarsal head, and heel.
RESULTS: Average detection accuracy of the smart shoes for the GCT was 79.9% (1st MH) and 82.2% (Toe), respectively. As the walking speed increased, the error tended to increase. In the PssP, average accuracy of the smart shoes was 93.4% (1st MH) and 95.3% (Toe), respectively. The accuracy was also slightly decreased as the walking speed was increased.
CONCLUSION: As a result, only two of the four sensors installed in smart shoes can determine the gait cycle and pattern. The detection accuracy of gait cycle at the Toe was higher than 1st MH, but the difference was not significant (average difference: 0.03 sec). Therefore, high detection accuracy can be expected even if the sensor is attached to either Toe or 1st MH.

DYNAMIC RSA AND OPENSIM: INVESTIGATION OF THE JOINT BIOMECHANIC MODIFICATIONS AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

BRAGONZONI, L.1, BONTEMPI, M.2, CASSIOLAS, G.3, LOPOMO, N.F.3, ZAFFAGNINI, S,1.2

1. UNIVERSITY OF BOLOGNA, 2. IRCCS ISTITUTO ORTOPEDICO RIZZOLI, 3. UNIVERSITY OF BRESCIA

INTRODUCTION:Anterior Cruciate Ligament (ACL) reconstruction is used to restore knee biomechanics after injury. Many studies have tried to support the clinical research by investigating the joint biomechanics after the ACL reconstruction. Among them, the Dynamic RSA seems to be able to achieve the accuracy level to leading the research to the final step. The aim of this study is to integrate the RSA, with the force platform data and process them with OpenSim to have a sensitive tool able to detect small variations of joint biomechanics.
METHODS: Nine patients with ACL-rupture were evaluated with dynamic RSA, connected to a force platform the day before the reconstruction surgery (PRE) and after 18 months of follow-up (FU).
Three different surgical techniques were used: NADB, SB, SBLP. The patients were asked to perform level walking with the ACL injured leg during the x-rays. A force platform, synchronized with the x-rays, acquired the ground force vector. The acquired data were then processed and the results were analyzed in OpenSim
RESULTS: Patients were divided by surgical technique and gender. Dynamical evaluations of the knees showed that the Female have a greater abduction moment (2.98 Nm) with respect to males (1.78 Nm). This is true for both PRE and FU and it was reported in the literature [1]. Patients treated with SBLP seems to better control knee movement and reduce the loading acting on the joint during the stance phase of gait (FU-PRE = -1.224 Nm). On the contrary, the SB had the worse stability (FU-PRE = 6.463 Nm).
CONCLUSION: Although at a preliminary stage, the present procedure appears to be a valuable tool for a complete and accurate evaluation of knee joint kinematics and dynamics. Deeper investigations will produce more accurate results on the differences between PRE and FU groups.

CHANGES IN EMG ACTIVITY OF RECTUS FEMORIS, ISOMETRIC FORCE OF KNEE EXTENSION AND LATERALITY AFTER SQUAT MASTERING PROGRAM – CASE STUDY

KRCMÁR, M., CHUDÝ, J., BIELIK, V., MUSILOVÁ, E., BUZGÓ, G.

FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION:Differences in muscle strength of lower extremities might potentially increase the incidence of sport specific injuries (1). In this study we track how the squat mastering program will change EMG activity of rectus femoris, maximal isometric force of knee extension and laterality of lower extremities.
METHODS: Two male subjects without previous experience with squat exercise were randomly divided into experimental (EXP) and control (CON) subject (EXP: age, 20.8 years; height, 185 cm; weight, 81 kg; CON: age, 19.9 years; height, 182 cm; weight, 82 kg). EXP subject performed 3-weeks deep squat mastering program which consisted of eleven training sessions aimed to master the squat, using unilateral and bilateral variations, without any attention for strength development. Pre- and post-training tests were: maximal isometric force of knee extension (ISOext90) in 90° angle of knee flexion, maximal isometric force of left and right limb during bilateral contraction (ISOextL90, ISOextR90) and lateral deficit ratio of lower limbs (LAT). These parameters were measured by "Knee dynamometer" device (S2P, Slovenia). EMG activity (maximal value - EMGmax and integrated EMG activity of full contraction – EMGint) of rectus femoris muscle of both legs was measured during the test by EMG Delsys Tringo Wireless System (USA). This paper was created with support of VEGA MŠVVaŠ SR and SAV č. 1/0333/18.
RESULTS: There were found changes of EMG activity and strength in EXP subject (followed squat mastering program) and CON subject (without squat mastering program intervention). In EXP ISOext90 increased by 11.5 % (+63.5 Nm), ISOextL90 increased by 15.9 % (+40 Nm), ISOextR90 increased by 7.9 % (+23.5 Nm), LAT strength difference decreased by 5,9 % (pre: 84,2 %, post: 90,1 %). In CON ISOext90 increased by 5.3 % (+40.7 Nm), ISOextL90 increased by 6.7 % (+26.1 Nm), ISOextR90 increased by 3.9 % (+14.5 Nm), LAT strength difference increased by 2.8 % (pre: 95.5 %, post: 93 %). In EXP EMGmaxL decreased by 2 % (-13.5 μV), EMGmaxR increased by 18.3 % (+76.2 μV), in CON EMGmaxL decreased by 42.5 % (-137 μV), EMGmaxR decreased by 35,5 % (-160 μV), in EXP EMGintL increased by 17.6 % (+71.4 μV.s-1), EMGintR increased by 7.7 % (+18.5 μV.s-1), in CON EMGintL decreased by 1 % (-2 μV.s-1), EMGintR decreased by 26.9 % (-68 μV.s-1).
CONCLUSION: EXP subject who participated in the 3-weeks squat mastering program had greater increment in selected parameters. It suggests that squat mastering program has positive influence on EMG activity of rectus femoris muscle and isometric force of knee

extension. Another positive effect is decreased in lateral strength difference ratio. We recommend a larger sample size to be included in the research to reach valid conclusions.

DYNAMIC KNEE VALGUS DETECTION DURING SQUATTING FOR UNSUPERVISED HOME TRAINING

VENEK, V.1, KREMSER, W.1, RIESER, H.1, SCHECHINGER, M.2, JUNGREITMAYR, S.2

1 SALZBURG RESEARCH, JAKOB HARINGER STRAßE 5/3, 5020 SALZBURG, AUSTRIA; 2 MYBODYCOACH - MOVEMENT EDUCATION AND SCIENCE, ROBINIGSTRAßE 13, 5020 SALZBURG, AUSTRIA

INTRODUCTION:Abnormal movement patterns such as the dynamic knee valgus (DKV) can lead to serious joint problems [1]. Pushing the knees too much inwards, e.g. during squatting, can occur particularly in unsupervised training. Thus, an affordable plug & play system should be developed to highlight DKV in real-time during exercise at home. Previous studies focused on assessing the squat quality using inertial measurement units (IMUs) to automatically categorize Single Leg Squat [2][3]; however, using IMUs requires expert knowledge in setup and data gathering and is as such not yet ready for everyday use.
METHODS: Therefore, we decided to investigate a camera-based system for DKV detection. After exploring the market, we decided on the Orbbec Persee, a 3D camera-computer system, and the Nuitrack skeleton tracking software. The proposed DKV detection algorithm uses the distance between the knee joints during the initial position and monitors it throughout the exercise. 41 subjects (23 female, 18 male, mean age 23.9±5.2 years) performed squats six times in front of the system. A sport scientist annotated the recordings to establish a ground truth about when DKV was occurring. Finally, the algorithm was evaluated by calculating the confusion matrix on both repetition- and subject-level.
RESULTS: Although the recall was over 70 % on both levels, the precision was about 40 % on subject-level. This means that although the algorithm detected most of the knee valgus positions correctly, it produces false positives as well.
CONCLUSION: The proposed DKV detection algorithm together with the Orbbec Persee were combined to a home training feedback system with telecoaching option. When an abnormal movement pattern is detected, a personal coach will be asked to verify the algorithm output. Since the system will be tested with over 100 people in the field, the DKV is only communicated to the personal coach if more than 20 % of the repetitions were classified as abnormal. Thus, less false positives can be obtained. Other exercises such as lunges were recorded of the 41 subjects and will be used for further analysis and optimization of the algorithm. In order to evaluate the effectiveness of the system on people's knee stability, the Y-balance test and the functional movement screen (FMS) hurdle step will be examined before and after the six-month trial.

CHARACTERISTICS OF MOTION-FREQUENCY IN LONG-TERM ATHLETES

ARAI, A., AKAMOTO, M.

DOSHISHA UNIVERSITY, OSAKA UNIVERSITY OF HEALTH AND SPORTS SCIENCES

INTRODUCTION:Long-term athletes tend to develop different forms, body shapes, and rhythms depending on the sports they play. In this study, we investigated the characteristics of specific adaptations affected by long-term participation in competitive sports. As a result of the better adaptation of athletes, some neuromuscular functions may be suppressed. In this study, we focused on the cyclic motion rhythm.
METHODS: Eighty long-term female athletes (6 groups: badminton, basketball, softball, track and field, swimming, and control) took part in this study. They performed four cyclic movements (walking, rope-jump, basketball dribbles, and side-step) with their own natural rhythms. In each trial, the motion of subjects was recorded for sagittal and frontal plane movements (2 video cameras were used; 60 fps and 240 fps) and each touchdown was confirmed.
We measured the motion-frequency of these cyclic movements using motion analysis software (Kinovea). The step frequency of the walking and rope-jump movements was measured from one touchdown to the next, the side-step frequency was indicated by each touchdown from the right side to the left, and the frequency of dribbles was measured from one hand touch to the next. Motion-frequency was calculated by number of the steps / time, and 10-step-frequencies were averaged. All motion-frequencies were calculated by extracting 10 sequences of steps/dribbles with a constant beat.
RESULTS: The swimming and control groups had a significantly lower walking velocity than the other groups ($p<0.01$). Additionally, the swimming group had a significantly lower walking frequency than all the other groups. The results of the side-steps and rope-jump movements were similar to those of walking. In the dribble - the only exercise involving the upper limbs - although the rhythm was easy to be prescribed by the fact that the ball bounces back, the swimmers' frequency was about 1 Hz close to the swimming rhythm. The swimmers seemed to be waiting for the ball to bounce back up, whereas the other group touched the ball in middle of bounce back up.
CONCLUSION: All the cyclic and rhythmic exercises showed a remarkably low motion-frequency for the swimmers. The low or high motion-frequency is considered to be a competitive feature in athletes.

DIFFERENCES IN LOWER LIMB MUSCLE STRENGTH AND POWER BETWEEN HIGH JUMP AND LONG JUMP ATHLETES USING REBOUND JUMP TEST

ZUSHI, A., KARIYAMA, Y.2, YOSHIDA, T.1, ZUSHI, K.1, KIGOSHI, K.1, OGATA, M.1

TSKUBA UNIVERSITY, YAMANASHI GAKUIN UNIVERSITY (YAMANASHI, JAPAN)

INTRODUCTION:In track and field events involving jumping, such as high jump and long jump, the stretch-shortening cycle (SSC) movement at the lower limb muscle-tendon complex is performed during the take-off phase. However, each event's take-off direction is different; thus, there are differences in characteristics of the SSC movement between both types of jumpers. Drop jump and rebound jump (RJ) tests are widely used to assess the SSC ability (Zushi et al., 1993;Flanagan EP. and Comyns TM. 2008). Therefore, we aimed to clarify the

differences between the high jump group (HJ) and long jump group (LJ) with respect to SSC movement characteristics by performance variables and kinetics of lower limb joint in the RJ test.
METHODS: RJ test was performed by 25 male jumpers (LJ:13, HJ:12). Three-dimensional coordinates during jumping were collected using a Vicon T20 system. Ground reaction forces were obtained with a force platform. RJ-index was calculated by dividing the jump height by the contact time in the RJ test. The Quick Motion Analysis System, which automatically calculates and presents data on the RJ performance variables and kinetic variables immediately after the test, was used to measure the work of the three lower limb joints. The IAAF score refers to the jump event performance that is calculated by the IAAF Scoring Tables of Athletics. Paired t-test was used to determine a statistical significance of the difference between the HJ and LJ ($p<0.05$).
RESULTS: IAAF score and RJ-index were not significantly different; the HJ and LJ showed the same level of IAAF score and RJ ability in this study. In addition, contact time of the HJ was significantly longer than that in the LJ. Moreover, in the HJ, the knee joint's negative and positive works and hip joint's negative work were significantly higher than the LJ. In contrast, in the LJ, ankle joint's relative work was significantly higher than the HJ.
CONCLUSION: Compared to the long jump event, the approach speed in the high jump event is slow and the contact time is long (Coh M, and Supej M, 2008). In addition, the high jump event involves take-off to the vertical direction. Therefore, it is considered that such characteristics affect the contact time in the RJ test and the kinetics of the lower limb joint. Accordingly, the characteristics of contact time and kinetics of the lower limb joint in the RJ that produce them are different depending on the type of event even if the IAAF score and the RJ index are the same.

RELATIONSHIPS OF FORCE ACTING ON THE CENTER OF GRAVITY TO RUNNING SPEED AND JUMPING DIRECTION IN RUNNING SINGLE LEG JUMP

SHIBATA, A., KIGOSHI, K., ENOMOTO, Y.

UNIVERSITY OF TSUKUBA

INTRODUCTION:Running single leg jump is one of basic motion for many sports. However, it has not been clear how running speed utilize jump performance effectively by take-off movement. In the take-off phase, the force acting on CG can be divided into the centripetal force that changes the direction of velocity and the tangential force that changes the magnitude of the velocity. There is no study which focuses on the effect of those forces for jump performance. The purpose of this study was to clarify the effect of centripetal and tangential forces on running speed and jumping direction in the take-off phase.
METHODS: The subjects in this study were 6 male jumpers. They asked to jump forward (H) and upward (V) as possible as they can with four different running speed (~4.0m/s; Slow, 4.5~5.5m/s; MidS, 6.0~7.0m/s; MidF, 7.0m/s~; Fast). Three-dimensional coordinates of the end points of the segments of the body were obtained using motion capture systems at 250Hz. The GRF was obtained by the force platform at 1000Hz. Coordinate data were smoothed using a Butterworth low-pass digital filter. The CG coordinates of the total body were estimated from the body segment parameters of the Japanese athletes. The GRF and gravity acting on the CG were divided into the centripetal and tangential component based on the direction of CG velocity, which are integrated during contact time to calculate the impulse. The force and impulse were normalized by the subject's body mass.
RESULTS: The contact time decreased significantly at Slow to MidF while it was not significant changed at MidF to Fast in each jumping direction. In the centripetal direction, positive impulse increased significantly at Slow to MidS in each jumping direction while it was not significant changed among other speed conditions [Slow-H; 2.6±0.2, MidS-H; 3.5±0.1, MidF-H; 3.6±0.4, Fast-H; 3.6±0.3, Slow-V; 3.4±0.2, MidS-V; 4.1±0.2, MidS-V; 4.1±0.2, MidF-V; 4.2±0.4, Fast-V; 4.0±0.3 (Ns/kg)]. The positive impulse of the tangential component decreased significantly at Slow to MidF in each jumping direction. Furthermore, negative impulse increased significantly at Slow to MidF in each jumping direction, however there is no significant difference at MidF to Fast. There are significant difference at peak positive centripetal force and peak negative tangential force in all conditions.
CONCLUSION: The impulse of centripetal components was occurred by the trade-off between the increase in peak force and decrease in contact time. The negative tangential impulse was increased as running speed increased. These results suggest that centripetal impulse is one of the essential factor to utilize running speed for jump performance although the change of CG velocity in the take-off phase occurred in higher running speed. Running jump should need the technique to utilize running speed for change in the direction by centripetal force for CG velocity in the take-off phase. This concept might be useful to evaluate the jump technique for coach and future study.

INFLUENCE OF OVERWEIGHT ON STATIC FOOT ANTHROPOMETRY AND PLANTER PRESSURE DISTRIBUTIONS DURING NORMAL GAIT IN JAPANESE ELEMENTARY SCHOOL CHILDREN

NOZAWA, T.1, HIRANO, T.1, FUJITO, Y.2, KIUCHI, A.1, SOMA, M.3, KASHIWAGI, Y.4, FUNATO, K.2

1: GRADUATE SCHOOL OF HEALTH AND SPORT SCIENCE, NIPPON SPORT SCIENCE UNIVERSITY, 2: NIPPON SPORT SCIENCE UNIVERSITY, 3: JUMONJI UNIVERSITY, 4: SENSHU UNIVERSITY

INTRODUCTION:Obesity and overweight are serious problem as one of the risk factors for disturbing normal growth and development in childhood. Deformity of foot structures and abnormal gait patterns were reported in sedentary obese adults. The aims of present study were to investigate the influence overweight on foot anthropometry during static standing as well as planter pressure distribution patterns during self-paced normal gait in Japanese elementary school children.
METHODS: 145 boys in elementary school 5 or 6 grade, finally thirteen overweight children (Age.12.0±0.5, 20.55<0.05.
RESULTS: In the static standing posture, the overweight group showed significantly larger anthropometric variables than those of normal weight group however, when the measured value was normalized as the foot length, no difference in foot anthropometry was observed between the two groups. In the dynamic foot measurement, CA, MF and PP in midfoot area indicated significantly large value in overweight group compared to normal weight group ($P<0.01$).
CONCLUSION: The overweight children also have experienced significantly higher pressure than normal weight children, suggesting that their midfoot may be exposed to increased stress and, in turn, vulnerable to bony fatigue and soft tissue damage in daily life. Overweight causes few influence on foot anthropometry during static standing but greater planter pressure particularly in midfoot in children.

FOOT STRIKE PATTERN DISTRIBUTION OF SPRINT RUNNING IN ELEMENTARY SCHOOL CHILDREN

YOSHIDA, T.1, TAKESHITA, T.1, NORO, H.1, KATO, R.1, TAGURI, A.1, HATA, K.1, KOKUBUN, K.2, FUKUNAGA, T.3, YANAGIYA, T.1
1.GRADUATE SCHOOL OF JUNTENDO UNIVERSITY 2.JUNTENDO UNIVERSITY 3.NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA

INTRODUCTION:In the recent related study of running, effects of foot strike patterns are focused on. Because of magnitude larger impact force immediately after foot contact of the ground, it is reported a higher risk of running-related injury (Lieberman et al, 2010) and/or lowering running performance in the rear-foot strike running compared with fore-foot strike running. Foot strike patterns is reported to shift from rear-foot strike to fore-foot strike as the running speed is increased. (Forrester and Townend, 2015). Although children were reported to contact with rear-foot, top level athletic sprinters were reported to much more contact with fore-foot strike during sprint running. However, it is not known about changes in foot strike pattern along with growth and/or development. Therefore, the purpose of present study was to investigate cross-sectional school grade differences in foot strike pattern for elementary school children.
METHODS: Sprint running time trial for 50m had carried out as one of the events of fitness test in public elementary school in Chiba prefecture of Japan. Sagittal running motion of 242 participants were recorded with a high-speed video camera from the left side of the runway. The width of angle view was 6 meters from 32m to 38m point from start line. Kinematics of running motion was analyzed using motion analysis software. In addition, foot strike patterns were classified to 3 types with fore-foot, mid-foot, and rear-foot. Running velocity, step frequency, step length, contact time, and flight time were measured from the frame of the movies.
Comparison of variables among three-foot strike patterns were used chi-square test methods. One-way ANOVA was conducted for comparison of running velocity, and multiple comparison test was conducted when the main effect was observed among grader level. In every case, the significance level was set to less than 5%.
RESULTS: There was a significant increase in height, weight, and step length, due to the grader increase. On the other hand, no significant changes to observed in step frequency, contact time, flight time and foot strike pattern due to the grader increase. The range of running velocity of children in this study was from 4.4 m/s to 6.0 m/s.
CONCLUSION: The previous study reported that foot strike pattern shifts from rear-foot strike to mid-foot and or fore-foot strike when running velocity increases (Forrester and Townend, 2015).. Moreover, the threshold at which foot strike pattern was reported as 5.3 m/s. However, the foot strike pattern of children had unchanged even if running velocity was over the threshold in this cross-sectional study.

IN VIVO GASTROCNEMIUS MEDIALIS ARCHITECTURAL PROPERTIES IN FEMALE ATHLETES WITH DIFFERENT FLEXIBILITY TRAINING BACKGROUND

DONTI, O., PANIDIS, I., TERZIS, G., BOGDANIS, G.C.
NATIONAL & KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION:Transient increases in joint range of motion (ROM) after static stretching are mainly due to increased stretch tolerance and changes in passive stiffness of the muscle and tendon unit (1). A recent short-term study in humans reported that 6 weeks of static stretching increased ankle ROM and medial and lateral gastrocnemii fascicle length and thickness (2). However, long-term joint ROM increases following static stretching in humans are not adequately documented, possibly because the characteristics of the stretching protocols used (e.g duration, intensity, volume) were not adequate to induce measurable changes (3). An alternative approach would be to examine populations with a chronic flexibility training background. The purpose of this study was to examine differences in gastrocnemius medialis (GM) architectural characteristics and ankle joint ROM, at rest and during 1 min of static stretching, between female athletes who have undergone long-term flexibility training and athletes who typically spend less time in stretching.
METHODS: Ten elite rhythmic gymnasts (age: 21.3 ± 1.6, height: 169.9 ± 2.9, body mass: 56.7 ± 8.4) were compared to ten national level volleyball athletes (age: 24.3 ± 4.7, height: 173.6 ± 4.3, body mass: 70.6 ± 14.7). Fascicle length, pennation angle and muscle thickness at the medial and the distal part of GM, and ankle ROM were measured with ultrasonography, at rest and during 1 min of static stretching.
RESULTS: At rest, rhythmic gymnasts displayed longer fascicles compared to volleyball athletes, at the medial (5.93 ± 0.27 vs 4.74 ± 0.33 mm, respectively, $p = 0.001$) and the distal part of GM (5.63 ± 0.52 vs 4.57 ± 0.51 mm, respectively, $p = 0.001$), smaller pennation angle at the medial part (22.4 ± 2.5 vs 25.8 ± 2.4°; respectively, $p = 0.001$) and greater ankle angle (121.7 ± 4.1 vs 113.2 ± 3.7°, respectively, $p = 0.001$). During the 1 min of static stretching, gymnasts displayed greater fascicle elongation at the distal part ($p = 0.026$), greater maximal ankle dorsiflexion ($p < 0.001$) and muscle tendon junction displacement ($p < 0.001$) with no difference between groups in pennation angles ($p > 0.145$), muscle thickness ($p > 0.105$), and fascicle elongation at mid-belly ($p = 0.063$).
CONCLUSION: These findings suggest that muscle architectural properties differ between athletes with different levels of flexibility and that there may be non-uniform adaptations along GM length. Longer muscle fascicles at rest and greater fascicle elongation at the distal part of GM may contribute to the greater ankle ROM observed in rhythmic gymnasts.

INTRAMUSCULAR SITE DIFFERENCE OF MUSCLE TENSION ON RECTUS FEMORIS DURING ISOMETRIC CONTRACTION WITH DIFFERENT MUSCLE LENGTH

TANAKA, S.1, IMAWAKA, T.2, YOKOZAWA, S.1, SRDJAN, D.3, TSUNODA, N.1
1: KOKUSHIKAN UNIVERSITY, , 2: JAPAN INSTITUTE OF SPORTS SCIENCE, , 3: TMG-BMC CO.,

INTRODUCTION:It is well known that the generation of muscle force depend on muscle length and size (1, 2). The muscle contraction sensor is possible to evaluate the muscle tension as a mechanical activity during contraction (3). It has been reported that signal by the Muscle contraction sensor was related to the elbow flexion force under the isometric contraction (3, 4). However, there are not so well known that the muscle contraction property during force generation using the Muscle contraction sensor. Therefore, the purpose of this study was to investigate the muscle contraction properties under the different muscle length conditions and site difference in intramuscular using the Muscle contraction sensor method.
METHODS: Eleven males were participated in this study. The knee extension torque under the isometric contraction was measured using a dynamometer. The measurement posture was two conditions, which knee joint angle flexed at 60 degrees with hip joint angle at 90 degrees, and knee joint angle flexed at 30 degrees with hip joint angle at 0 degrees. At the same time, muscle tension as an index of mechanical activity at proximal, muscle belly and distal sites on the rectus femoris were measured by the Muscle contraction (MC) sensor

(TMG-BMC co). And, the electrical muscle activity was measured by the surface electromyography. These measurement parameters were calculated the mean values based on each 5% per MVC of the knee extension torque.
RESULTS: The muscle tension at the proximal site showed a most high value compared to the muscle belly and distal site in either conditions. On the other hand, there was not so much observed the site difference of the electrical muscle activity in the intramuscular. Furthermore, the muscle tension at proximal, muscle belly and distal sites of the rectus femoris indicated approximately same value in two muscle length conditions, respectively.
CONCLUSION: In this study, intramuscular site difference of muscle tension on the rectus femoris was observed. This tendency was observed both contraction and extension of the muscle length conditions. In previous study, it has reported that the site difference of activity on the rectus femoris during contraction was observed (1, 2). Therefore, it was suggested that the MC sensor method can be an effective method for evaluating muscle contraction properties under the different muscle length conditions and intramuscular.

DO SYMMETRIC EXERCISES OF ABDOMINAL MUSCLES CAUSE THEIR SYMMETRICAL ACTIVITY?

SZPALA, A., RUTKOWSKA-KUCHARSKA, A.

UNIVERSITY SCHOOL OF PHYSICAL EDUCATION IN WROCLAW

INTRODUCTION:The aim of the study was to assess the electromyographic activity (EMG) of the rectus abdominis (RA) muscle in various curl-up exercises. This exercise consists of bending the trunk from the back lying to a position where the lumbar region of the spinal column remains in contact with the ground. It is a popular exercise used in training programs to prevent low back pain (LBP). One of the causes of LBP is the asymmetric pressure of the vertebral bodies on the intervertebral discs, resulting from the asymmetry of the muscles stabilizing the spine, which is why in training programs aimed at the "healthy spine" attention is paid to the symmetric exercises of this group of muscles.
METHODS: Twenty students of the physical education faculty participated in the research. The subjects performed curl-up abdominal muscle exercises with four symmetrical positions of the upper and lower limbs (exercise 1 - "curl-up without stabilization"; exercise 2 - "curl-up with stabilization"; exercise 3 - "curl-up legs on the chair "; exercise 4 -" curl up legs up"). The EMG of the RA muscle was recorded on the right and left side, both in the upper and lower part. Additionally, a electrogoniometer was placed on the subjects trunk, which made it possible to analyze the EMG signal separately in the flexion and extension movement. Recorded data were normalized to EMG activity measured under maximum voluntary contraction (MVC).
RESULTS: The symmetry evaluation of EMG signal took place in two stages. First, the activity of the examined muscles was compared between the right and left side separately for the upper and lower part, and then the upper and lower parts were compared on the right and left side of the body. The conducted analysis showed the asymmetry of RA muscle activity between its left and right side in the upper part, both in the flexion and extension movement ($p = 0.0001$). Asymmetry was also dominant in the lower part of RA in exercises 1, 2 and 3. In exercise 4 - "curl-up legs up" symmetry of the lower part was found in the flexion phase ($p = 0.503$) and extension ($p = 0.102$). In turn, the comparison of activity between the upper and lower part on the right side of the body revealed asymmetry in 3 exercises: in exercises 1 and 3 in the extension phase ($p = 0.0003$), and in exercise 4 in the flexion phase ($p = 0.001$). However, the comparison of the amplitude level of the EMG signal between the upper and lower part on the left side of the body in each exercise showed asymmetry in both phases of movement ($p = 0.0001$).
CONCLUSION: The curl-up exercises performed in our studies were symmetric exercises. In addition, the symmetry of these exercises increased the symmetrical position of the upper and lower limbs during exercise. It could therefore be assumed that symmetrical exercises will affect the symmetry of muscle electrical activity. The observed asymmetry may be the result of the phenomenon of compensation of electrical activity of the RA muscle.

DOES THE FEMORAL MULTI-RADIUS DESIGN ALLOW A MORE STABLE TKA KINEMATICS?

ZINNO, R., BRAGONZONI, L., CARDINALE, U., BONTEMPI, M., MARCHEGGIANI, M.G.M., ALESI, D., PIZZA, N., AGOSTINONE, P., ZAFFAGNINI, S.

ISTITUTO ORTOPEDICO RIZZOLI

INTRODUCTION:TKA posterior stabilized (PS) is the best surgical choice when the posterior cruciate ligament is unfunctional. The central cam stabilizes the anterior-posterior translation. Moreover, the multi-radius feature of the investigated implant makes a smooth transition throughout the range of motion and minimizes the anterior movement. The aim of this study is to describe the in vivo kinematics of the knee after PS Rotating Platform TKA implantation Attune (TM) Knee System, DePuy Synthes, J&J, Warsaw, IN, USA) using dynamic RSA.
METHODS: A cohort of 8 patients (mean age 67.6 yo) was evaluated at 9 months of follow up after the TKA. The patients were asked to perform a lunge: from the neutral position, the patient makes a step, then flexes, and return to the stand position.
Kinematical data were evaluated relating to the flexion angle versus Internal-External rotations, Varus-Valgus rotations and Antero-Posterior translations and and low-point contact areas of the femur with respect to the tibia, using the Grood and Suntay decomposition.
RESULTS: During the lunge phase, from 20° to 40° of knee flexion, an internal rotation of about 3° was evaluated. Then, from 40° to 80° an external rotation was observed. During the flexion, from 20° to 80° the kinematics indicates a posterior translation of the femur respect to the tibia. Then it turns to an anterior translation during the extension. Low Point kinematics showed a slight medial pivot from 50° to 55° of knee flexion.
CONCLUSION: The kinematical results obtained with dynamic RSA showed that this prosthesis model is not affected by the paradoxical anterior translations during lounge motion task reported by other designs.
Further studies are needed to evaluate the impact of different TKA designs on clinical results.

PRINCIPAL COMPONENT ANALYSIS REVEALS THE PROXIMAL TO DISTAL PATTERN IN VERTICAL JUMPING IS GOVERNED BY TWO DEGREES OF FREEDOM

CUSHION, E.J., WARMENHOVEN, J., NORTH, J.S., CLEATHER, D.J.

ST MARYS UNIVERSITY

INTRODUCTION:The successful completion of motor tasks requires effective control of multiple degrees of freedom (Bernstein, 1967), with adaptations occurring as a function of varying performance constraints (Newell, 1986). In this study we sought to compare and characterise the emergent coordination strategies employed in vertical jumping under different task constraints (with arm swing-CMJas and no arm swing-CMJnas).
METHODS: Thirty eight participants performed five maximal vertical jumps without the use of an arm swing. Twenty two of these participants also performed five maximal vertical jumps with an arm swing. Kinematic data was collected using a Vicon motion capture system with fourteen LED cameras tracking the reflective markers at a sampling frequency of 200Hz. Kinetic data was collected via two force plates positioned flush to the laboratory floor. A standard inverse dynamics analysis was performed to attain sagittal plane lower limb joint moments. Individual principal component analysis (PCA) was performed on joint moment data of the hip, knee and ankle for each participant. In addition, a group analysis was conducted with a PCA carried out on all joint moments from all participants. These analyses were performed for both jumping conditions.
RESULTS: When considered individually, up to only two principal components (PCs) were required to describe 90% of the variance in the data. Data from each individual PCA showed a significantly greater amount of variance was observed in PC1 and the sum of PC1 and PC2 in CMJnas than CMJas ($p = 0.05$, $p = 0.00$ respectively). When all joint moment data was combined in the same PCA, three PCs were retained for CMJas condition and two were retained for CMJnas condition.
CONCLUSION: When considering all PCA performed it was interesting to observe for all comparisons 90% of the variance in the raw data could be described by at most three PCs. This demonstrates a remarkable degree of similarity in the pattern of movement production both within and between individuals when performing the action under differing task constraints. The two PCs required when describing CMJnas pattern demonstrates this movement is governed by only two degrees of freedom, rather than the typically reported three degrees of freedom (proximal to distal extension at hip, knee and ankle). The third PC required in CMJas condition is suggested to highlight the inter-individual variability within this movement.

REGULAR ADAPTED PHYSICAL ACTIVITY CAN INFLUENCE THE PELVIC TILT IN UNILATERAL TRANSFEMORAL AMPUTEES

SOBOTKOVA, I., HOSKOVA, B.

CHARLES UNIVERSITY

INTRODUCTION:Amputation is irreversible loss of integrity of the organism [2]. It causes threefold loss in terms of function, sensation and body image [1]. Despite using LL prostheses, it can lead to problems with postural alignment, muscle imbalances and strains, gait abnormalities [1]. Transfemoral amputation irreversibly influences the muscle balance [4]. The higher level of the amputation, bigger influence on the muscle balance [2]. Postural asymmetries might lead to chronic conditions which result in limitation of mobility and restriction of ADL [3]. The aim of our research was to find out if it is possible to change pelvic tilt (in frontal and sagittal plane) in unilateral transfemoral amputees with regular adapted physical activity and influence positively their ADL.
METHODS: 9 unilateral transfemoral amputees (5 males, 4 females, age 34,5±7,5) were intentionally chosen, 5 of them completed whole program. Pelvic tilt in frontal (Angle F) and sagittal plane (Angle S) of each amputee was measured before and after intervention. Angle F and Angle S were measured when they were standing with and without prosthesis. 3D positioning tracking system (Qualisys) was used. The adapted exercise program (AEP) lasted 4 months. Each amputee who went though whole program was interviewed (subjective data collection).
RESULTS: In-depth interview: after 1st month of regular AEP all participants felt no low-back pain, pain got much better or didn't appear as often in their ADL. After program completion they felt "straighter", in better physical condition, ADL (e.g. walking) didn't feel as difficult as before starting AEP. One participant felt that AEP positively influenced her relationship. Angle F: Participant no. 2, 3 and 4 show positive improvement in Angle F elimination. Participant no. 1 has contradictory results (most likely caused by her imbalanced mind on the day of post-intervention measurement). Participant no. 5 improved but not significantly when standing with prosthesis. Most likely due to his trained body and regular PA he has been doing. Angle S: Significant pelvis tilt change in participant no. 2 (middle-aged female, inactive, anterior pelvic tilt) when standing with prosthesis and when standing without prosthesis. Other participants had physiological (neutral) pelvic tilt in sagittal plane so the pre and post intervention difference is moderate. Participant no. 1 tended to bigger anterior pelvic tilt during the 2nd measurement than during the first one when standing with prosthesis but it was most likely influenced by her mental state at the moment. Later, when she calmed down, the results show significant difference between pre and post intervention values in Angle S when standing without prosthesis.
CONCLUSION: It isn't possible to generalize the level of pelvic tilt change but it is clear that the pelvic tilt might be influenced with regular adapted physical activity in unilateral transfemoral amputees and it can positively influence their ADL and higher their quality of life.

THERE ARE TWO FORMS OF ISOMETRIC MUSCLE FUNCTION – ENDURANCE TIME AND MECHANOMYO-/-TENDOGRAPHIC PARAMETERS OF MUSCLE SPEAK FOR A DISTINCTION BETWEEN A HOLDING AND A PUSHING FORM

SCHAEFER, L., BITTMANN, F.

UNIVERSITY OF POTSDAM

INTRODUCTION:In sport science isometric strength is usually measured by pushing against a stable resistance. However, subjectively one can perform isometric muscle action either by pushing against a stable resistance or by resisting an impacting force, thus, by holding isometrically. Research showed, inter alia, that EMG is similar for both tasks, but the time to sustain the holding task is briefer compared to the pushing task at low intensities (1-4). The purpose of this study was to investigate whether or not the two tasks of isometric muscle action – the holding (HIMA) vs. pushing (PIMA) one – differ at higher intensities.
METHODS: Ten subjects performed two isometric tasks at 80% of the MVIC (15s- and fatiguing trials). The tasks were realized by means of a pneumatic system. During HIMA the subject had to resist the impacting force of the pneumatic system in an isometric position. During PIMA the subject worked isometrically in direction of elbow extension against a stable position of the system. The signals of pressure, force, acceleration and mechanomyography/-tendography (MMG/MTG; piezoelectric sensors) of the elbow extensor (MMGtri/MTGtri)

and the abdominal external oblique muscle (MMGobl) were recorded and evaluated concerning the duration of sustaining the force level (force endurance) and the characteristics of MMG-/MTG-signals.
RESULTS: During HIMA the subjects showed a significantly shorter time of stable isometric position (19±8s) compared to PIMA (41±24s; p=.005). The longest isometric plateau amounted to 59.4% of the overall duration time of isometric task during PIMA, whereas during HIMA it lasted 31.6% (p=.000). The frequency of MMG/MTG did not show significant differences. The power in the frequency ranges of 8-15 Hz was significantly higher in MTGtri performing HIMA compared to PIMA (not for MMGs). The amplitude of MMG/MTG did not show any significant difference over the total duration time. Looking only at the last 10% of duration time (exhaustion), the MMGtri muscle showed significantly higher amplitudes during PIMA.
CONCLUSION: The results confirm previous research and indicate that during isometric muscle action two forms can be differentiated by quantitative parameters. The earlier exhaustion during HIMA vs. PIMA could speak for different neuromuscular control strategies of both tasks, as already proposed by (4). A different metabolism could be relevant, too. The capability of holding or resisting, respectively, could be a relevant parameter concerning injury mechanisms.

DEVELOPING THE JORDANIAN VERSION OF THE TALENT DEVELOPMENT ENVIRONMENT QUESTIONNAIRE FOR SPORT

ALTWASSI, S., MARTINDALE, R., MAKHADMEH, N., QASIM, S., SPROULE, J., ANDRONIKOS, G.
EDINBURGH NAPIER UNIVERSITY

24rd annual ECSS Congress Prague/ Czech Republic, July 3-6/ 2019
Developing and Using the Arabic Talent Development Environment Questionnaire for Sport within a Jordanian Football Context
Altwassi S. Martindale R. Makhadmeh N. Qasim S. Sproule J. Andronikos G.
INTRODUCTION:
As elite sport standards are becoming more professional, understanding effective talent development environments are becoming a bigger focus for many sport organisations. In response to the need to improve the dissemination of evidence-based practice, the Talent Development Environment Questionnaire (TDEQ) was developed (Martindale et al., 2010). To date, the TDEQ has been used to understand environments across a number of sports and countries. However, there is a need to develop an Arabic version, which can be used to understand environments in 22 countries across the world. This study aims to develop an Arabic TDEQ and evaluate practice within clubs and academies in a Jordanian football context.
METHODS: Three hundred and nineteen players aged 12-18 from clubs and academies in Jordan participated. The TDEQ-5 (Li et al., 2015) was translated in line with standard recommendations. A confirmatory factor analysis was carried out, and differences between clubs and academies were analysed.
RESULTS AND CONCLUSION: The results revealed that the Arabic TDEQ had adequate psychometric properties. Interestingly, the relative strength of the TDEQ factors was the same across clubs and academy environments, with Long Term Development being the strongest and Holistic Quality Preparation the weakest factor. Even so, academies were significantly stronger across each of the TDEQ factors ($F(313,5) = 7.193$, $p < .01$), namely; Long Term Development (A = 5.33; C = 5.02); Support Network (A = 5.08; C = 4.76); Communication (A = 5.02; C = 4.69); Alignment of Expectations (A = 4.77; C = 4.26) and; Holistic Quality Preparation (A = 4.28; C = 3.90). Through item-by-item analysis it was revealed that the academies had fourteen strength items and one weakness item, while the clubs had five strength and five weakness items. These results have implications for Jordanian football talent development environments. Furthermore, the Arabic TDEQ can be recommended for use in the other Arab countries due to their similarity in culture, tradition and religion for research and applied purposes.

PHENOMENOLOGICAL STUDY ON TRAINERS PRACTICAL KNOWLEDGE FOR UNDERSTANDING OF MOVEMENT

MAKOTO, S.
NATIONAL INSTITUTE OF TECHNOLOGY, NUMAZU COLLEGE

Introduction
The first step in movement instruction is to grasp the current problem of each learner by looking at the movement execution and to think about the method for acquisition. Such a problem has been taken up as a problem of movement observation in the past. In this movement observation, knowledge on the movement technique is required for the trainer. Such knowledge has been clarified by natural scientific method as the result of sports science. It has been pointed out that there are three hierarchies (Judgment of correctness, Point out shortcomings, Point out of method) in the understanding of the movement by trainer for movement instruction (Kaneko, K. 1990). However, it is impossible to judge how exercisers perceive their movement execution as their own senses from the external movement process. In other words, in order to point out the method in the third hierarchy, it is necessary to understand the sense of accomplishment of the learner. Therefore, in previous study (Kaneko, K. 1987), when trainer observes movement execution, the necessity of empathic observation through transplanting the body is stated. However, even if trainer performs empathic observations, it is not certain whether trainer can understand movement execution of learners exactly. The purpose of this study is to clarify the importance of substitution ability and interview ability as practical knowledge to correctly understand learners movement from empathic observation.
Method
In this study, I analyze the understanding of learner by experienced leader using phenomenological methods. From this analysis result, I clarify the structure of understanding and the function of substitution and interview abilities in movement understanding. Through these, I refer to the importance of substitution ability and interview ability in practical knowledge of leaders.

Conclusion
From the results of reflective analysis in the phenomenological method, it became clear that the structure of movement understanding will be accurately made by complementing the result of empathetic observation through interview and substitute work. At the same time, it became clear that not only the observation ability but also the substitution ability and the interview ability have a great influence on the practical knowledge of the leader for others understanding. Furthermore, from these results, I was able to confirm the possibility of approaching from the viewpoint of substitution ability and interview ability, to construct methodology for leaders to increase practical knowledge.

RELATIONSHIP BETWEEN MOVEMENT AND FITNESS TEST CHARACTERISTICS DURING UNIVERSITY SOCCER GAMES

FUKUSHI, N.

KEIO UNIVERSITY

【Introduction】
Although the use of scientifically-based methods for sports training and practice is actively promoted, the most familiar and simple scientific approach to instruction is to quantify the physical strength and ability of the athlete via physical fitness tests. However, it is difficult to clearly define and quantify competitive skill in a soccer competition, and it is unclear what kind of physical strength test should be used. According to a questionnaire survey on the Japanese university soccer teams, about half of these teams did not perform physical fitness tests (Fukushi et al.,2015). Therefore, the purpose of this research is to propose instructional physical fitness test items that are convenient, efficient and based on the characteristics of movement, which are tracked by GPS devices during actual soccer game.
【Methods】
Subjects included 33 male soccer players (19.9±1.07years old). The physical fitness test items used a total of 6 types of 50-m running (10, 20, 30, 40m transit time), vertical jump, bounding, standing broad jump, Arrowhead agility test, Yo-Yo intermittent recovery test level 2 (YYIR2). A 15Hz GPS device (SPI-Pro X2) was used to measure motion during the game. The extracted items were top speed (km/h), total mileage(m), number of sprints(24km/h≤), high intensity (15km/h≤)m, and sprint(24km/h≤)m. In teams of statistical analysis, Pearsons fractional correlation coefficient was used to examine the relationship between physical fitness test results and items of movement extracted during the game. The statistical significance level was set to less than 5%.
【Results and discussion】
A significant correlation was found between top speed and 20m transit time(r=-0.346,p<0.05), top speed and 30m transit time(r=-0.409,p<0.05), top speed and 40m transit time(r=-0.463,p<0.05), top speed and 50m transit time(r=-0.509,p<0.01), sprint count and YYIR2 (r=0.452,p<0.01), and sprint m and YYIR2 (r=0.444, p<0.01).
In soccer, the intermittent ability to perform frequent, repetitive, high-intensity exercise is considered to be a very important measure of physical strength. Excellence in sprinting ability is also related to competitive performance (Bangsbo et al.,2018). In this study, the additional events reported for fitness testing, with respect to movement characteristics during a soccer game, were the YYIR2, which reflects intermittent high-intensity exercise ability, and 50-m running, which reflects sprinting ability. Therefore, we considered these two events as the most important ones to adopt for instruction. In future, we will further strengthen this conclusion by using physical fitness tests and accumulating additional supporting data.

EFFECTS OF PHOTOTHERAPY ON PERFORMANCE AND RECOVERY DURING A BADMINTON CHAMPIONSHIP: A RANDOMIZED, DOUBLE-BLINDED, PLACEBO-CONTROLLED CLINICAL TRIAL

DE PAULA RAMOS, S., BARAZETTI, L.K.

UNIVERSIDADE ESTADUAL DE LONDRINA

INTRODUCTION:Badminton is an indoor racket sport that involves a wide variety of short-duration, high-intensity actions, rapid arm movements, and jumps . Official Badminton competitions are performed from 3 to 5 consecutive days, and the athletes play 1 to 3 games a day, increasing the risk of cumulative fatigue and exercise-induced muscle damage. Phototherapy can be used in exercise as an ergogenic and recovery method, preventing exercise-induced muscle damage (EIMD) and fatigue, and improving performance.
METHODS: Twenty five male athletes, engaged in single and double categories, participated in the study. The athletes were randomly allocated to Phototherapy (LEDT, n= 11) and Placebo (n=14) groups. Phototherapy (630nm, 4.6 J/cm2, 6J per point) was applied to 17 points on the lower limbs and dominant shoulder, every day before the first game. Blood samples for creatine kinase analysis (CK) and muscle soreness (MS) were collected before the first game (Pre), after the final game (Post), and after 24 h, during 4-days of competition. The squat jump (SJ), countermovement jump (CMJ), and Handgrip strength (HS) were recorded before the first game (Pre) and after each game throughout the competition. Differences between treatments and moments were evaluated through repeated measures ANOVA and Two-way ANOVA tests, considering P<0.05.
RESULTS: No effects for treatment were detected in CK levels or MS, immediately Post games and after 24 h. Athletes who played three or more games per day presented improvement in SJ height, with an effect of LEDT treatment (F=5.0, P=0.04). After successive games, CMJ performance improved in both groups without effects of LEDT. HS also increased after successive games in both groups with effects for LEDT after successive games (F=11.6, P=0.006).
CONCLUSION: The main finding of this study is that phototherapy using light-emitting diodes (LEDT) applied before successive Badminton games could maintain or improve performance in SJ and HS over successive games. However, discrete effects were detected in variables commonly associated with loss of performance due to exercise-induced muscle damage, such as CK and muscle soreness, since athletes did not present significant signs of muscle damage.

COACHES' NATURALISTIC DECISION MAKING AROUND INJURY IN AN ELITE SOCCER YOUTH ACADEMY.

SOMERS, S., BUCHANAN, N., SWINTON, P.

ROBERT GORDON UNIVERSITY

INTRODUCTION:Naturalistic decision making [NDM] encompasses rapid cognitive processing of information in order to make complex decisions and actions performed during high-pressure, real world environments (1). In sport the importance of NDM is paramount however in terms of managing injury surprisingly little evidence exists. The current research explores the use of NDM in elite youth academy soccer coaches.
METHODS: The critical decision audit [CDA] (2) was employed to uncover a range of NDM process for monitoring and controlling instances of downregulation in youth players. To explore coach incidence management, data was collected over two six-week cycles during the beginning of season. In total, fourteen interviews were conducted with the CDA until saturation of data was reached for seven youth academy coaches. For the analysis, Lyle's (3) NDM model provided a framework from which to frame the thematic coding of the interview data. A total of 81 raw themes, 19 Higher Order Themes (HOTs) and 3 General Dimensions (GDs) were generated, including GD1) 'Past and Future Considerations'; GD2) 'Smart Procedures'; and GD3) 'Adapting to Injury'.
RESULTS: Results indicate youth coaches undertake NDM via a number of key processes these are: scanning (noticing potential events), which is influenced by GD1 (e.g. 'Understanding From Past Experiences' [HOT2]) and GD2 (e.g. 'Tactical Probing of Player' [HOT10]). Similarly, the second stage of the model comprising interpretation (problem framing) is also influenced by GD1 (e.g. 'Stage of Footballing Variants' [HOT4]) and GD2 (e.g. 'Individual Player Knowledge' [HOT10]). In both stages, GD1 may be viewed as fixed constraints, whereas, GD2 may be viewed as flexible tools to compliment experiences of coaches to enhance their ability to notice and suitably frame events. The third stage of the contextualised model includes decision types which is influenced by GD3 (e.g. 'Medical Staff Recommendations' [HOT17]) and highlights the considerations that the coach uses to make effective decisions once a triggering threshold has been reached. NDM is therefore conceptualized as a complex process that is dynamic and does not follow fixed sequential processes.
CONCLUSION: Results identify coach NDM around injury regulation to possess a range of central components aligning with the Lyle NDM model, however specific components are deemed more fluid and dynamic than expressed by Lyle. For example, NDM was deemed to operate over multiple time frames at micro, meso and macro scales. NDM therefore can be deemed cyclical, devoid of a fixed outcome, but rather driven by continuous scanning, interpretation and modification of decision frames over time.

WHAT MAKES COACHING PROFESSIONAL DEVELOPMENT EFFECTIVE? :THE COACHING LADDER AS A FOUR-PHASE MODEL OF COACHING EXPERTISE.

KITAMURA, K., DEXIA, Y.

NIHON UNIVERSITY, TOHOKU UNIVERSITY

Introduction
When investigating the state of coaching expertise, it is necessary to pay attention not merely to individual coaching experience but also to contextual factors. A contextual factors and individual learning phase and experience on coaching has been raised as a means to grasp the longitudinal aspect of growth as an expert coach.
The study argues for a broader understanding of experience; placing experience within the context of reflection, connection with others and their individual understanding about coaching. Accordingly, through detailed analysis, this study aims to clarify how the contextual factors effect the individual learning phase and experience on coaching expertise in a qualitative analysis of coaching ladder.
Method
1. Subjects
A total of 15 expert coaches with experience of full-time coaches of professional clubs or Olympic teams in Japan were chosen as participants for this study. Those selected for the target group had to meet the following three basic criteria: 1) Having 60% or more of their work allocated to coaching tasks, 2) Having minimum five years of top-league level coaching experience, 3) Consented to participate in the study. The average age of participants was 47.8 years old.
2. Research Method
Data were collected through a series of in-depth, semi-structured, open-ended interviews, observations, and documents. Data analysis was arranged into hierarchical categories following the qualitative data analysis conducted by Côté, et al. (1993), after discussion with several collaborators. Interviews were between 60 and 80 minutes in length. The interviews were systematically transcribed verbatim from the IC recorder immediately after the completion of each interview. A total of 271 meaning units were extracted from the transcription data, and various tags were assigned. In the end, 255 meaning units and tags were used as the subject of analysis in our investigation.
Results and Discussion
A total of 255 meaning units were classified into the following seven sub-categories: self-acceptance, abstraction of persistence to personal experiences, context of relationship building, carrier transition from athlete to coach, tacit knowledge, activated knowledge, and holistic practical knowledge. These were then finally classified into the following three categories which were crucial for the coaches to develop their career as coaching ladder: reflection of coaching mind and behavior, refinement of communication style, and cultivation of practical wisdom. The more progress coaches made, the wider they played a crucial role to support their athlete's performance development in a manner that made an optimum psychological environment for athletes.
Conclusion
The strong relationship between the perceptions of the concepts on how coaches evaluated their coaching activities in relation to performance enhancement of athletes and how this support affected their development of coaching excellence.

AEROBIC AND ANAEROBIC ENERGY PRODUCTION DURING TIME-TRIALS OF SIMULATED DOUBLE-POLING ON A SKI-ERGO BY COLLEGIATE MEN

LI, Y.1, LI, B.1, WANG, X.1, HOLMBERG, H.C.2

1SHANGHAI UNIVERSITY OF SPORT, 2MID SWEDEN UNIVERSITY

INTRODUCTION:Determination of aerobic and anaerobic contributions to energy production in connection with any form of exercise or sport provides meaningful insights into their physiological profile. Previously, these energy contributions in connection with high-intensity efforts of various durations (i.e., from 30-s to several minutes) and types (e.g., running, rowing, cycling) have been reported (1). However, corresponding information concerning double-poling is lacking, hindering comprehensive understanding of this special form of exercise involving primarily the upper body (2). Accordingly, our aim here was to provide such information.
METHODS: 20 male volunteers (21.2±1.6 yrs, 177.5±6.4 cm, 70.0±9.8 kg) studying physical education in college performed four time-trials of double-poling skiing (30 s, 1 min, 2 min, and 5 min) on a SkiErgo. Portable spirometry (K4b2, Cosmed, Italy) was utilized to measure pulmonary gases. Capillary blood taken from earlobe was analyzed for lactate (Biosen C_Line, EKF, Germany). The procedure based on the fast component of oxygen debt following exercise was utilized to calculate the aerobic and anaerobic energy contributions (3). In addition, the function y=23.355*LN(x)+41.02 proposed by Li et al., where y is the relative aerobic contribution in % and x the duration of the time-trial in min was utilized to calculate the relative aerobic contribution (1).
RESULTS: As the duration of exercise increased, the energy contribution from the alactic anaerobic pathway did not change significantly (26.0-30.1 kJ, $p>0.05$), while the contribution from the lactic anaerobic pathway rose gradually from 28.3 kJ at 30 s to 47.0 kJ at 1 min ($p<0.05$) and the aerobic contribution increased dramatically (13.0-249 kJ, $p<0.05$). The relative aerobic contribution was 18.3±3.8%, 38.1±3.4%, 58.1±3.2% and 76.4±3.2% in 30 s and 1, 2 and 5 min, respectively (significant difference between each two durations, $p<0.05$) and, moreover, at 30 s and 1 min differed significantly from the estimates calculated using the function (29.7% and 40.0%, $p<0.05$).
CONCLUSION: The relative aerobic and anaerobic energy production during time-trials of simulated double-poling skiing was dependent on the duration, with an increased aerobic contribution with longer duration. However, the relative aerobic energy contribution in 30 s and 1 min appeared to be significantly lower than the estimates provided by the function proposed by Li et al. which should thus be applied only with caution to any given type of exercise (e.g., double-poling) for any given duration (e.g., 30 s and 1 min).

FOOTBALL PLAYER'S COGNITION OF SKILLS

KOAKUTSU, A.1, HASEGAWA, N.2, MOMOSE, Y.3, CHIBA, G.1

1: NATIONAL DEFENSE ACADEMY , 2: TOKYO KASEI UNIVERSITY , 3: TOKOHA UNIVERSITY

INTRODUCTION Skills (how to acquire and perform techniques) are a very important factor in football games. It is also essential for coaches to grasp player's cognitive structure of skills. This study aims to develop a cognitive scale and demonstrate a structure of skills for football players.
METHODS The study used a questionnaire answered by 1173 male Football players (341 junior high school students, 464 high school students and 368 college students). The questionnaire consisted of 72 questions about skills. The data collected was subjected to exploratory factor analysis, reliability analysis and confirmatory factor analysis by structural equation modeling.
RESULTS Four factors were extracted from the results using exploratory factor analysis. In the next exploratory factor analysis, the number of items of each factor is made equal, and each item was subordinated to each factor. The result also showed that each item had a factor loading amount over .40 and a simple structure. The Cronbach's α of each factor was .87, .83, .88 and .70, starting from factor 1. The fit coefficients by confirmatory factor analysis were sufficient (GFI=.939, AGFI=.916, CFI=.948, RMSEA=.066). All pass coefficients that observed variables from latent variables were significantly ($p<.001$) and showed positive values more than a medium level (.47−.84).
DISCUSSION The factors extracted by exploratory factor analysis were called Cognition to training and game, Cognition to learning strategy, Cognition to mastery of skills, and Cognition to result and ability. We judged that the scale was sufficiently reliable, because the Cronbach's α was over .70. The result of confirmatory factor analysis showed sufficient construct validity of the model, which comprised of 16 items of the four factors. Football player's cognition of skills consisted four factors. The resulting scale had sufficient reliability and validity, and we provided suggestions about using this scale.

RELATIONSHIP BETWEEN DEVELOPMENT OF DANCER AND META-COGNITIVE VERBALIZATION

CHIHARU, O.

OCHANOMIZU UNIVERSITY

Introduction
As Parviainen points out, professional dancers are able to develop their mind and body while continuing their performance activities. According to Parviainen, this process is "practice of the self", which is not only the development in technique but also the in mental and physical consciousness. Among these, there have been interviews with dancers about changes in body consciousness. Based on the above, the purpose of this study is to investigate the mastery of the physical consciousness of professional dancers in terms of the ability to verbalize, and to consider the relationship between the meta-cognitive verbalization and the development of dancer's cognition on the body.
Methods
In this study, the interview surveys using Personal Attitude Construct (PAC) analysis method (Naito,1993) were conducted in 2013 and 2017. We aim to verify the influence of dancer's accumulated experience on the survey response. The interviewee (female in her 20s) was a major member of Japanese contemporary dance company.
The first procedure, the associative stimulus sentence was set as follows: When you're asked "What makes an ideal dancer?", what kind of words and images come to you? Fill in the order of the words and images that came to mind. Then, the target was asked to (1) order sorting, and (2) identify the paired-words rating of distance the similarity rating between the items. Based on the data, the cluster analysis based on the similarity distance matrix was performed.
Results and discussion
The number of associative items in Survey I was 10 and Survey II, 20. For the number of clusters, 4 clusters (Survey I) and 10 clusters (Survey II) were precipitated. The increase in the number of items was seen in Survey II. This indicated that the evaluation of the similarity became more complex. From this, it was shown that the body sense of the dancer was verbalized in a more detailed manner by accu-

mulating the stage experience. Suwa analyzes the effects of meta-cognitive verbalization in bowling and darts, and considers the ability of meta-cognitive verbalization to be closely related to technical improvement in sports (Suwa, 2005, 2007).
This study allowed to visualize the verbalized items by focusing on one dancer longitudinally. It can be said that the results indicate the significance of verbal guidance as well as verbal feedback in a dancer's own words in the field of development of professional dancers.

EXPLORING SPORT COACHES' EXPERIENCES OF USING A CONTEMPORARY PEDAGOGICAL APPROACH TO COACHING

STONE, J.A., ROTHWELL, M., DAVIDS, K.
SHEFFIELD HALLAM UNIVERSITY

Introduction
Contemporary coaching approaches are becoming more prominent in academia, however, there is still limited take-up by practitioners [1]. This results in a disconnect between what contemporary empirical research suggests as sound pedagogical principles, and what coaches adopt in practice [2]. Research has investigated why sport coaches continue to use traditional reproductive pedagogical methods [3]. However, limited research has explored the insights and experiences of high-performance coaches who are employing contemporary methods in practice. Hence, this study aimed to (i) explore the insights of high-level coaches who are adopting contemporary approaches to understand why these coaches have eschewed more traditional methods, and (ii) gain information on their experiences when employing these contemporary approaches in their practice.
Method
Fifteen sports coaches (9 to 28 years professional experience) from individual (5) and team sports (10) were interviewed. Coaches ranged from working within national level sports teams, coaching Olympic athletes and being employed within professional sport organisations. Participants were purposively sampled based on their adoption of contemporary models of learning in their pedagogical practice, defined as athlete-led, non-linear, individualised, and focused on problem solving [4]. Interviews ranged from 35 to 99 minutes and were transcribed verbatim. A thematic analysis of the qualitative data was conducted.
Results
The thematic analysis revealed 58 lower-order themes, 12 higher-order themes, which were organised into 3 dimensions; (i) factors underpinning model of learning; (ii) model of learning; and (iii) responses to contemporary approaches. Coaches reported a typical culture of traditional methods of learning within their sports. However, they believed traditional approaches were not effective in developing athlete performance. Hence, they adopted a non-linear, individualised, adaptive approach, emphasising representative learning designs [4]. Typical reactions to this approach resulted in resistance from stakeholders (e.g. athletes, parents, NGBs) [3]. However, coaches continued to use this approach and expressed how positive reactions emerged over time with effective communication with stakeholders being critical for acceptance of their model of learning.
Conclusion
Despite the well-accepted theoretical ideas of contemporary models, coaches face a hard challenge implementing these new models of coaching in practice. Continued integration between experiential and empirical knowledge may increase the acceptance of contemporary pedagogical approaches and encourage the uptake of these models of learning.

IMPROVEMENT OF PROBLEMS WITH THE FIELD PRACTICE OF SPORTS INSTRUCTORS FOR THE ELDERLY

KIM, S.H.
MOKPO NATIONAL UNIVERSITY

The purpose of this study is to identify problems with field practice in the last stage of the national certification of sports instructors for the elderly and propose improvement measures. For this purpose, the study looked into the current state and problems of field practice in the certification and proposed a set of improvement measures. The subjects included four instructors at field practice institutions Data was collected with an open-ended questionnaire. The field practice logs of trainees were also used as reference data. Collected data was analyzed in content. The findings were as follows: first, the study examined the current state of field practice and found that trainees searched for an institution of field practice themselves. They would first choose an institution close to their residence, and institutions had a strong tendency of accepting trainees based on relations with them. Secondly, the first problem identified in field practice was a mismatch between practice events and the qualification events of trainees. The next problem was the shortage of preparation by the trainees. Since field practice is the last stage in a national certification, trainees need to show an active and passionate attitude. It has been pointed out that trainees should not use field practice as a chance to just pass the time. The final problem concerned the meaninglessness of field practice. Trainees might find field practice meaningless since there were many instructors with a long career in the field. Finally, there should be a match between the qualification events of trainees and their field practice events so that field practice will provide field-based meaningful education in the training process for certification. The next improvement should come from the differentiation of field practice. The last is that trainees should change their mindset. They should be armed with a sense of responsibility, passion, and sincerity as they further their learning in the field. It has been five years since the reorganization of the certification system. It is time to examine institutional issues with the certification system in-depth and take measures to supplement them.

A STUDY ON THE EFFECTIVENESS COACHING WITH "INNER FRONT SUPPORT ON LB – CLEAR HIP CIRCLE THROUGH HSTD WITH FLIGHT TO HANG ON HB (SCHAPOSCHNIKOVA)"IN UNEVEN BARS OF WOMEN'S ARTISTIC GYMNASTICS

MURAYAMA, D.

SHIGAKKAN UNIV.

INTRODUCTION:Acquisition and mastery of technique occupy the core of artistic gymnastics training. It is important to conduct a study that examine how athletes understand movement effectively. It is critical to build the correct "movement conception" for the acquisition of technique (Grosser & Neumaier, 1982).
"Inner front support on LB – clear hip circle through hstd with flight to hang on HB (Schaposchnikova)" in Uneven Bars is positioned as D difficulty according to the "Code of Points" published by the International Federation of Gymnastics (FIG). This element has been acted by many players in recent years. In 2017, the structure system of this element was arranged by Nakasone(2017) in Japan, and the relation with other element became clear. However, there is no research on the coaching method of this element in 2019.
The objective of this research was to develop a coaching method for mastery of motor imagery by player, using the example of skill acquisition process of this element, and to verify the method's effectiveness.
METHODS: The method was; 1) The configuration of the stage practice to the success of the element, 2) To clarify the relevance of movement sense in each practice stage, 3) To analyse from the viewpoint of phenomenological movement theory.
RESULTS: Stage practice was 10 steps. As a result of sensory association at each stage exercise, many important sensory factors were revealed. In particular, it was found that supporting(assisting) technologies by coaches are important.
CONCLUSION: From the phenomenological consideration it was concluded that the following points are important; 1) to perceive the direction to pop out, 2) degree of direct intervention by coaches. By this research, Effective knowledge was obtained in women's gymnastics competition.

THE EFFERCTS OF ELITE TRIATHLON EXPERIENCE ON SOCIAL ADAPTION AFTER RETIREMENT

CHANG, D., CHOI, S.

KOREA NATIONAL SPORT UNIVERSITY

Introduction
The purpose of this study is to explore how the athletes experience in elite triathlon athletes social adaptation after retirement has helped them to enter a society successfully.
Methods
In order to accomplish this research purpose, 10 retired athletes who have experience of elite triathlon player and who are not in the physical education field after retirement are selected as research participants, and Data are collected through in-depth interviews, analyzed through grounded theory method of qualitative research. With the open coding, axial coding, and selective coding of Strauss & Corbin (2014) grounded theory method, The results of the study, the effect of the elite triathlon player experience on successful social adaption, are as follows.
Results and discussion
First, since childhood, they were used to a hierarchy through group life and seniority, and this helped interpersonal relations in social adjustment process after retirement.
Second, athletes who have experienced triathlon as a challenge to the limits of human beings have been helped in psychological aspects such as challenge spirit in retirement, efforts to achieve it, and persistence.
Third, the players who experienced triathlon, which requires a great amount of physical strength, showed a great deal of physical strength in social adaptation after retirement.
The researchers said that triathlon athletes who are about to retire need to broaden their horizons and learn after retirement(Coakley 1983; Greendorfer & Blinde, 1985)..

IDENTIFICATION OF THE PHYSICAL AND TECHNICAL SKILLS FOR THE DETECTION OF TALENTED TENNIS PLAYERS (11-14 YEARS OLD): FACTORIAL ANALYSIS

GEORGATOU, E., BOLATOGLOU, T., DONTI, O., APOSTOLIDIS, N.

UNIVERSITY OF ATHENS

INTRODUCTION:The purpose of this research was to evaluate the physical abilities, the technical skills and the anthropometric characteristics of young tennis athletes (11-14 years old) and furthermore to identify the most significant abilities for the talents initial detection.
METHODS: One hundred athletes (aged 11-14) from different tennis clubs in Athens were measured in their anthropometric characteristics (body weight, body height and length of the arms) and also were tested on a series of physical fitness and technical skill tests (maximal isometric strength, sprint speed, lower limbs power, medicine ball throwing, and sport-specific balance tests). Furthermore, athletes subjected to (International Tennis Number, ITN), technical assessment tests of the main forehand and backhand drives, forehand and backhand volley and serve. Firstly, Pearson correlation analysis was applied where the variables related to physical abilities and technical skills were correlated and then factorial analysis was performed with the pivotal axis rotation.
RESULTS: The results revealed that velocity correlated high with backhand (p=.004) and forehand (p=.036). Strength of the lower limbs was correlated with forehand cross (p=.0017), with forehand in the line (p=.003), with service (p = .001) and forehand (p=.003). Speed was associated with service (p=.000) and with forehand in the diagonal (p=.0043). Agility (clockwise) correlated with forehand (p=.015), with

forehand in the straight line (p=.019), with backhand in the straight line (p=.0360). Finally, lower limb power was associated with backhand (p=.018) and service (p=.000), while balance was correlated with service (p=.013).
Furthermore, the results of the factorial analysis displayed that the arms length (.932), body height (.928), body mass (.435) and velocity (.391) presented significant loadings and so they appeared to be the most important physical factors for identifying talented tennis players. Additionally, as far as the technical skill factor is concerned, it was confirmed that all the strokes except the backhand volley are important in order to select a tennis player. Specifically, significant loadings presented forehand in the diagonal (.665), backhand (.641), backhand in the diagonal (.621), forehand down the line (.578), service (.539) and forehand volley (.475).
CONCLUSION: According to the results of this study, coaches will be able to identify a possibly rising tennis player with developed anthropometric characteristics by measuring the speed as well as technical skills in tennis strokes. The results of the research highlight the importance of selected anthropometric characteristics of the athletes, the speed they develop, and the excellent technical execution of the basic strokes except for the backhand volley with respect the aim of detecting and preparing talented tennis athletes.

A QUALITATIVE STUDY ON THE COACHING VIEW OF A WOMAN LEADER OF THE JAPANESE TEAM FOR THE OLYMPICS: FOCUSING ON ARTISTIC SWIMMING COACHING

MITSUI, R., MIZUOCHI, F., KITAMURA, K.

1:NIHON UNIVERSITY 2:NIHON UNIVERSITY 3:NIHON UNIVERSITY

INTRODUCTION:Men greatly outnumber women among sports leaders. In Japan, Kanaya(2015) created a scheme for supporting strategic reinforcement measures for women contenders. In the report, she mentioned "increase of women sports leaders", "making it possible for women coaches to handle both their career and their private lives such as marriage and raising children", and "improvement of the social evaluation of women contenders and coaches" as challenges against competition environment around women contenders and leaders. Although sex difference is widely recognized, less women leaders play active roles in the situation of coaching because of various reasons, and thus less knowledge is accumulated on the feature of coaching by women leaders as well as its effects. This study aimed to visualize what perspective an excellent woman coach has on coaching by analyzing and surveying the coaching view of a woman coach who has gained experience by serving as a coach of the Japanese artistic swimming team for the Olympics and has trained many swimmers to achieve outstanding track records.
METHODS: This study surveyed a woman coach (Coach A) of the artistic swimming. She has a 48-year coaching career and is the manager of an artistic swimming club that has produced Olympic medalists. She has also served as the Japanese team's head coach for the Olympics several times and her team and swimmers won medals. Interviews were held with her three times, in a face-to-face, in-depth, and semi-structured way. The length of the interviews totaled 65 minutes. The utterance data gained from the interviews were then analyzed qualitatively.
RESULTS: Thirty-seven meaning units were gained from the interview data. They were classified into eight subcategories of "assuming that coaching does not get ones message across", "coaching is fascinating", "reflecting on ones own coaching", "creating a mechanism for learning", "understanding leaning from swimmers perspective", "capturing movement", "knowing the starting point of the movement", and "taking the viewpoint of others", which were then grouped into three categories of "having a basis as a coach", "getting the swimmers ready for learning", and "concretizing learning".
CONCLUSION: From the analysis, it became clear that Coach A assumed that her coaching action did not get her message across. She also prepared the environment for the swimmers to learn in order to concretize their learning.

CONTRIBUTION OF COLLEGE STUDENT LEADERS' CONSCIOUSNESS TOWARDS PARTICIPANTS' INTENTION TO CONTINUE ATTENDANCE IN COMMUNITY SPORTS CLASSES FOR CHILDREN

NAMIKA, M., AYA, M., KENTARO, T., TOSHIYUKI, M., KENYA, K.

NAGASAKI INTERNATIONAL UNIVERSITY

INTRODUCTION :
It is known that using sports resources in university (i.e. researchers, students, facilities) improves the sports environment of the neighboring community. Many sports classes have been held by universities for community residents. A problem dealing with these sports classes, especially in rural areas, is their continuation caused by decline in attendance. In this study, we looked at a sports class managed by a university in Japan which used college student leaders to coach children in the local community. The purpose was to clarify the contribution of college student leaders coaching consciousness towards the children's intention of continued attendance in the sports class.
METHODS :
The sports class was held for 20 times during the year. The duration of each class was two hours and the content of the classes was planned and managed by several college students. The total number of subjects who participated in the classes 20 times was 330 for the children and 197 for the college student leaders. At the end of each class, the children who had participated in the class were asked to answer their intention to continue the class using a five-point scale. For college student leaders, the scale to measure the competency of coaches (Takamatsu & Yamaguchi, 2015) was used to observe their consciousness for coaching after the class. The contribution of the college student leaders' coaching consciousness towards the children's intention to continue attendance in the sports class was investigated using linear regression analysis.
RESULTS :
The children's intention to continue attendance in the sports class was affected by the college student leaders' coaching consciousness such us "field management" ($r=.51$, $p<.05$) and "coaching skills" ($r=.56$, $p<.05$). The contribution ratio was 26% for "field management" and 31% for "coaching skills".
DISCUSSION :
It is suggested that the coaching consciousness of college student leaders, such us "expertise of coaching event" and "ambition for coaching", affected participants' intention to continue attendance in community sports classes for children. The result indicates the importance of expertise, even in community sports classes which provides multiple events.

HOW TO RECORD TRAINING LOADS IN ATHLETICS? THE ELABORATION AND CONTENT VALIDATION OF A CATALOG OF TRAINING MEANS FOR SPEED TRACK EVENTS.

SZMUCHROWSKI, L.A.1, SOARES, G.A.1, SLEDZIEWSKI, D.2, PEDROSA, G.F.1, SILVA, R.A.D.1, SCOTT, A.1, PRUDÊNCIO, M.V.1, MOTTA-SANTOS, D.1

1.LOAD EVALUATION LABORATORY, SCHOOL OF PHYSICAL EDUCATION, PHYSICAL THERAPY AND OCCUPACIONAL THERAPY, FEDERAL UNIVERSITY OF MINAS GERAIS, BELO HORIZONTE, MG, BRAZIL, 2.AWF WARSOW, POLAND.

INTRODUCTION:Many coaches are guided by empirical evidence at the moment of planning the training loads. Also, many times, these training loads are not record for posterior analysis of the training process. A scientific instrument elaborated and validated could help coaches in planning, registration and analysis of sports training load. Athletics is a sport composed by events of running, jumps and throw. Amongst the running events, the speed events are the most popular and are composed of 100, 200- and 400-meters dash. The present study aimed to elaborate and assess the content validity of a catalog of training means for speed track events.
METHODS: A group of ten expert coaches elaborated a catalog of exercises through interviews, answering which exercises are used in the training of technical, coordinating and physical capacities for sprinter athletes. Two groups of raters, one with a high level of academic degree and other with less level, evaluated content validity indicators as Clarity of Language (CL), Practical Pertinence (PP) and Theoretical Relevance (TR). The group of raters with a high level of the academic degree associated the elaborated exercises to physical training methods and intensity levels and the dimension of each exercise. The coefficient of content validity (CCV) was used as a tool to statistically measure the values found for CL, PP, and TR. The dimension was determined by means of scores assigned on a four-point scale and the level of concordance among judges in choosing the physical training methods and intensity levels was measured by the Kappa Coefficient.
RESULTS: A catalog containing 85 exercises was elaborated, but ten were eliminated from the catalog by presenting CCV to PP or TR below the cut-off point. The final catalog was composed of 75 training means, being 16 general, 24 special and 35 specifics and presented satisfactory CCV values. The whole catalog presented a 0.87 CCV value. The level of concordance among judges presented moderate (.577 for physical training methods) and substantial (.713 for intensity levels) agreement results for the analyses performed.
CONCLUSION: According to the results, content validity has been established for training means and this catalog can be a useful tool for speed track coaches at the moment of selection, recording and analysis of training loads.

THE FACTORS THAT AFFECT GOAL TIME IN TEAM PURSUIT SPEED SKATING

KOBAI, H.

AIZAWA HOSPITAL

INTRODUCTION:In the Team Pursuit, Japans ladies team won the gold medal at the Pyeongchang 2018 Olympic games. They have also reclaimed the gold at the 2019 ISU World Single Distance Championships. In mens competitions, though Japans team didnt get on the medal podium, it has reached the 5th in Pyeongchang Olympics, and the 4th at 2019 ISU World Single Distance Championships. By these results, the Team Pursuit is recognized as one of Japans strongest sporting event throughout the world. It is also noteworthy that the Japanese skaters are improving in the individual racing programs. However, despite the fact that it comes behind in the individual records, the teams are able to race at equal or even better levels in the Team Pursuit. This shows that the strategies and tactics are very important in the Team Pursuit, and that the Team Japan excels in it, compared to the other teams.
METHODS: This research program continues to study the effective strategies that would reduce the goal time of the Team Pursuit event over the past few years. I have analyzed the experiments, such as, wind tunnel experiments at the Japan Institute of Sports Sciences, or the Local Position Measurement System, installed at M-Wave in Nagano prefecture.
RESULTS: • Coursing that would minimize course-losses
• Averaged pacing allocation
• Method of changing at the lead skater rotation in the team line
• Maintaining the form of three skaters in line without losses
it became obvious that these are the effective factors in order to shorten the goal time. According to the wind tunnel experiment, by making the height of postures the same height as the leading skater, and setting the distance from the front running skater 1 meter long, the air resistance decreases by 50%, comparing it at the time of solo skating. However, if the distance from the front skater is set to 1.30 meter, there is not much difference observed in air resistance from the time of solo skating. When the three skaters are beautifully in line, the air resistance is halved. Yet it became clear that the effect disappears and the air resistance becomes the same as the solo skating, by just positioning 40cm next to the front skater. Also, as the result of measurements by Local Position Measurement System, at the change of leading skater, it became clear that it is important that *all the skaters keep the same speed without change of the speed, and the change must be done quickly in a shortest of time. In addition to these, as for the smaller details in order to shorten the goal time, we could also point out, the technical skating characteristics of consisting team members, how to select the order of leading skater exchange, etc.
CONCLUSION: Including above mentioned contents, this study reports on the factors that would affect the goal time in the Team Pursuit, which are thoroughly and generally examined. We also put the actual results and circumstances at the international competitions into our consideration.

COMPARING SIMPLE AND CHOICE EYE-HAND RESPONSE TIME AMONG NOVICE AND ELITE KARATE ATHLETES WITH NON-ATHLETES

LIU, Y.H.1,2, SEE, L.C.1,2, CHANG, S.T.3, LEE, J.S.2, SHIEH, L.C., NING, Y.L.8, LIM, A.Y.1, CHEN, W.M.1

1:CHANG GUNG UNIVERSITY, 2:CHANG GUNG MEMORIAL HOSPITAL, 3:CHUNG YUAN UNIVERSITY

INTRODUCTION:Karate is a popular combat sport involved in many international sporting events. Simple and choice response time (RT) are important determinants for karate competition. Studies showed notable controversy on the discrepancy in RT among different levels of karate skill. This study aimed to compare simple and choice RT among elite and novice karate athletes with non-athletes in college.
METHODS: We recruited three groups from colleges: elite karate athletes (n=28), novice karate athletes (n=34) and non-athletes (n=97). RT was measured by using FITLIGHT Trainer System, for both dominant and non-dominant hands in five conditions: simple RT at zero and shoulder distance (SRT_zero, SRT_shoulder), choice RT at zero, shoulder and random distance (CRT_zero, CRT_shoulder, CRT_random).

RESULTS: SRT_zero were 335.43±73.05ms, 306.33±47.05ms, and 292.33±45.4ms, while CRT_zero of dominant hand were 423.7±63.58 ms, 376.28±61.38 ms and 352.11±35.9 ms for non-athletes, novice and elite karate athletes respectively. Elite karate group was faster in simple and choice RT than non-athletes. Novice karate group was faster in only choice RT ($p<0.01$ for all conditions). When compared between two karate groups, the elite group was faster in CRT_random compared to the novice group ($p<0.001$).
CONCLUSION: Karate athletes had faster RT compared to non-athletes. Elite athletes were faster than novice athletes in choice RT.

Disability Sport and Physical Activity

PHYSICAL ACTIVITY AND THEIR DETERMINANTS IN CHILDREN AND ADOLESCENTS WITH AUTISM SPECTRUM DISORDER

JIANG, S.Y., HU, Y.H., HU, Y.T., PAN, C.J., PAN, P.Z., PAN, C.Y.
NATIONAL KAOHSIUNG NORMAL UNIVERSITY

Introduction
Low levels of physical activity (PA) and high levels of sedentary behaviors (SB) are associated with short- and long-term health consequences from early childhood, through childhood and adolescence. Social and behavioral deficits characterized in autism spectrum disorder (ASD) appear to be associated factors that limit opportunities for participating in PA among this population (Pan, 2009). However, estimates of PA and SB in children with ASD varied across studies (Jones et al., 2017).
Methods
Sixty-eight youths with ASD, aged 6-17, participated. The demographics (parenting structure, family income), youths behavioral and clinical profile (sedentary pursuits, comorbidities, medication use, therapy receive) were surveyed, and the PA data as objectively measured using an Actigraph GT1M/GT3X on the right hip for seven consecutive days were collected. One-way analysis of variance was performed to compare means of PA and SB variables in age groups (6-8 years, 9-11 years, 12-14 years, 15-17 years) as well as family income (low, medium, or high). Independent t-test was conducted to evaluate PA and SB across other determinants. Pearsons correlations were used to examine any relation between PA and SB, and the multiple liner regression was used to predict PA and SB from the variables significantly associated with it. Statistical significance level was set at $p < .05$.
Results
The main findings were that (a) there were significant differences between age groups for overall PA ($F = 8.28$, $p < .01$) and the level of PA during weekends ($F = 13.35$, $p < .01$), with the minimum PA level in 15 to 17-year-old group for both PA variables, (b) the single-parented youths showed a significantly less overall level of PA during weekends compared to the youths in two-parent families ($t = -2.13$, $p < .05$), (c) sedentary pursuits during weekends was significantly higher in the group of youths diagnosed comorbidities ($t = -2.27$, $p < .05$), and (d) age ($\beta=-0.45$, $t = -4.09$, $p < .01$), household structure ($\beta=0.25$, $t = 2.13$, $p < .05$), and comobidities ($\beta=0.27$, $t = 2.27$, $p < .05$) were predictors in the PA and SB of youths with ASD.
Discussion
Findings stressed the need for improving PA programs, particularly for older youths with ASD. Our observations also suggest that for a higher level of PA and a lower level of SB in youths with ASD, they should be provided with activity opportunities according to their sociodemographic profile and day of the week.

AEELEROMETER-ASSESSED PHYSICAL ACTIVITY AND SEDENTARY TIME IN CHILDREN AND ADOLESCENTS WITH AUTISM SPECTRUM DISORDER

CHEN, P.L., JIANG, S.Y., PENG, Y.H., LEE, H.J., LEE, P.C., PAN, C.Y.
NATIONAL KAOHSIUNG NORMAL UNIVERSITY

Introduction
The beneficial effects of physical activity (PA) on health for both children and adolescents are well known (WHO, 2010). Youths with autism spectrum disorder (ASD) might be at particular risk for inactivity due to social and behavioral impairments associated with the condition. To design PA interventions for youths with ASD, it is first necessary to know levels of PA and how PA is influenced by different factors, such as age and day of the week. This information is important for researchers developing and refining interventions for increased PA and reduced sedentary time in youths with ASD.
Methods
A sample of 68 males with ASD, aged 6-17 years, was recruited. Participants were given verbal and written instructions on wearing the accelerometer in an elastic belt around the waist for 7 consecutive days during all waking hours except during water activities. Outcome variables derived from the accelerometer data were (a) time spent in light-intensity PA (LPA), (b) time spent in moderate-intensity PA (MPA), (c) time spent in vigorous-intensity PA (VPA), and (d) sedentary time. Daily sitting behaviors, known as sedentary pursuits (e.g., television viewing, computer use, and reading) were also recorded using the activity log. Mixed design of two-way ANOVAs were used to compare the levels of PA and sedentary pursuits. The probability level was set at $p < .05$.
Results
The primary findings were that (a) weekday VPA was significantly higher for age group 6-8 years than age group 9-11 years ($F=3.39$, $p < .05$), and weekend VPA was significantly higher for age group 6-8 years than the other age groups (9-11, 12-14, and 15-17 years) ($F=9.67$, $p < .01$), (b) VPA of age groups 12-14 ($F=23.62$, $p < .01$) and 15-17 ($F=11.76$, $p < .05$) years during weekdays was higher than that during weekends, and no day-of-week VPA differences in age groups 6-8 and 9-11 years was found, (c) weekend sedentary time of age groups 6-8 and 9-11 years was more than age group 12-14 years ($F=8.55$, $p < .01$), and no age group differences for weekday sedentary time

was observed, (d) sedentary time of age group 12-14 years during weekdays was higher than that during weekends ($F=15.21$, $p < .01$), and sedentary time did not differ between weekdays and weekends in the other age groups, and (e) regarding weekday sitting behaviors, age group 6-8 and 9-11 years spent more time in television viewing than age group 12-14 years ($F=6.67$, $p < .01$), and age group 15-17 years spent more time in reading than the other age groups ($F=5.24$, $p < .01$).
Discussion
Future interventions to increase PA and decrease sedentary time in youths with ASD should be tailored to this population, and effective intervention directed at factors associated with age and day of the week are needed.

INCREASED SCHOOL-BASED PHYSICAL ACTIVITY IMPROVES CARDIORESPIRATORY FITNESS BUT NOT TOTAL PHYSICAL ACTIVITY AND SEDENTARY TIME IN 8TH GRADE ADOLESCENTS.

BRATLAND-SANDA, S., SCHMIDT, S.K., REINBOTH, M.

UNIVERSITY OF SOUTH-EASTERN NORWAY

INTRODUCTION:Physical activity (PA) level declines from childhood to adolescence, yet it is not known at what age the decline is happening or the course of the decline (Dalene et al., 2018) . Several studies have shown that school-based PA is beneficial for improving fitness and reducing risk of metabolic syndrome in children (Daly-Smith et al., 2018). However, studies on school-based PA in early adolescence are lacking. The aim of this study was therefore to examine possible changes in overall PA, moderate-to-vigorous physical activity (MVPA), sedentary time and cardiorespiratory fitness (CRF) following increased school-based physical activity among 8th grade adolescents.
METHODS: A total of 242 8th graders from five intervention schools (n=104) and ten control schools (n=138) participated in this quasi-experimental study (mean age 13.2±0.3 years). The intervention schools aimed to achieve a total of 59 minutes/day with PA using physically active learning (PAL, 27 minutes/day), active recess during lessons (5 minutes/day) and physical education (27 minutes/day). The control schools had physical education only. Data were collected at baseline (September 2017) and in the end of the school year (May and June 2018). Physical activity level (counts per minute and minutes per day with moderate-to-vigorous physical activity (MVPA)) and hours per day of sedentary time was assessed using ActiGraph GT3x. CRF was assessed through Andersen-test.
RESULTS: Fourty percent of the participants met the PA recommendations at baseline with no differences between intervention and control groups. There were no baseline differences in overall physical activity (counts/min), MVPA (min/day) sedentary time (hours/day) or CRF between participants from the intervention schools and the control schools. Boys had higher CRF than girls in both intervention ($t=4.48$, $p=0.001$) and control schools ($t=2.33$, $p=0.02$). No baseline differences were found in physical activity level and sedentary time between boys and girls at intervention schools, control boys had higher overall physical activity level ($t=4.45$, $p=0.001$), higher MVPA ($t=4.03$, $p=0.001$) and less sedentary time ($t=3.17$, $p=0.002$) compared to control girls. Overall physical activity, MVPA and sedentary time did not change from baseline to posttest in either intervention or control schools. Both intervention girls and boys improved CRF ($t=2.02$, $p=0.04$ vs. $t=2.48$, $p=0.02$) this change was not detected in control girls and boys.
CONCLUSION: Compared to studies on 9-year and 15-year old (Dalene et al., 2018), there was a very low percentage meeting the national recommendations for PA in children and adolescents. The lack of changes in total PA, MVPA and sedentary time indicates that other strategies are needed to improve adolescents' participation in PA. The increase in CRF despite unchanged PA implies important health benefits and suggests need for focus on intensity rather than duration of school-based PA.

MUSCLE ACTIVITY TIMING IN ELITE HANDCYCLING

KRATZENSTEIN, S., BRÜCKNER, J.P.

KIEL UNIVERSITY

INTRODUCTION:In hand cycling, there is still insufficient muscle activation data in novice and elite athletes, which can be used to determine an effective propulsion from muscle activity patterns. We aimed to provide this comparison by replicating existing data of novice athletes and adding the study of an elite athlete.
METHODS: The muscle timing was analysed during an incremental test using electromyography. Activity on- and offset was definded at a 15% threshold of each cycle's (n=30) maximum muscle activity. Biceps brachii (BIC), triceps brachii (TRI), posterior deltoid (TRD), anterior deltoid (DEA), upper trapezius (TRA) and pectoralis major (PEC) were analyzed as the main power producer during peadling. The novice group consisted of three subjects with no experience in hand cycling. A test day at least 3 days prior to the study provided all novices the opportunity to get familiarized with the handling of the bicycle. At the time of the study, the elite athlete was a member of the German Paralympic Team. He was classified as paraplegic with impairments corresponding to a complete lesion from T11 or below and no lower limb function (H4). The test protocol included an initial load of 40 W and a stepwise increase of 20 W every 5 min. The cadence had to be maintained between 80 and 90 rpm.
RESULTS: The results showed differences in inter-muscular coordination between the elite and novice hand cyclists. Although the distinction between active and inactive phases was already evident in novice data, the activation pattern of the elite athlete showed an even clearer delineation between the two phases. At 100 W the active phase was found to be 26% (PEC, TRI) to 113% (DEA) longer for novices than for the elite athlete. These time windows remained different also at maximum load, where muscle firing lasted still 7% (TRI) to 53% (DEA) longer than the elite athlete's activity. Since the elite cyclists activation windows remained stable until maximum load, the maximal signal amplitude at increased up to 220% of the 100W stage.
CONCLUSION: The inter-muscular coordination of the elite hand cyclist showed a shortening of the active phase, resulting in a longer recovery phase when compared to the novice cyclists. The athlete responded to the increased load with increased activation and recruiting of muscle fibres. This, however, still happened within a shorter time window than in the novice hand cyclists. Furthermore, the lack of co-activation of the antagonist muscles, shows the ability of the athlete to control unnecessary degrees of freedom of movement even under higher loads. In training the muscle timing with regard to the duration and the crank position should be considered to ensure sufficent passive and therefore recovery phases during pedaling. In future studies, the effect of handicap severity and crank frequency must be studied in greater detail.

EFFECTS OF ACUTE EXERCISE ON ERROR MONITORING DURING TASK SWITCHING IN CHILDREN WITH ATTENTION-DEFICIT/HYPERACTIVITY DISORDER: A PRELIMINARY STUDY

TSAI, Y.H., HUNG, C.L.

NATIONAL TAIWAN UNIVERSITY

INTRODUCTION:Previous studies have shown deficits in error monitoring in children with attention deficit hyperactivity disorder (ADHD). However, whether the deficit in error monitoring can be ameliorated by an acute bout of exercise remained unexamined. Error-related negativity (ERN) is an event-related potential component which has been associated with error monitoring. The main purpose of this study was to examine the effects of acute exercise on error monitoring during task switching in children with ADHD.
METHODS: Sixteen children with ADHD performed a task switching paradigm after 30 min of moderate-intensity aerobic exercise on a treadmill and after control sessions (watching videos while seated) in a counterbalanced order on separate days. The task switching included two conditions; the pure condition required participants to perform the task on the same rule whereas the mixed condition required participants to perform the task on two alternating rules. Task performance were recorded using STIM™ system and electrophysiological devices simultaneously. The ERN was extracted from the incorrect trials with amplitude quantified as the maximum negative deflection between 0 and 250 ms post-response in the average waveforms.
RESULTS: There were no significant differences in ERN amplitude between acute exercise and control sessions.
CONCLUSION: These preliminary results suggest that a single bout of acute exercise might have no beneficial effect on error monitoring during task switching in children with ADHD. Given the small sample size and relatively small number of incorrect trials, which may undermine the power to detect significant effect and reduce the signal to noise ratio of ERP, respectively. The result of the present study should be considered preliminary and treated with caution. Future studies on this topic should take these issues in consideration.

AUDIOSPATIAL COGNITIVE ABILITY OF BLIND SOCCER PLAYERS —SOUND SOURCE LOCALIZATION BY VISUALLY IMPAIRED AND SIGHTED PLAYERS—

WATANABE, M.1, YAMADA, T.2

1: TSUKUBA INTERNATIONAL UNIVERSITY, 2: HUMAN INFORMATICS RESEARCH INSTITUTE, NATIONAL INSTITUTE OF ADVANCED INDUSTRIAL SCIENCE AND TECHNOLOGY

INTRODUCTION:Blind soccer is a form of soccer played by teams of five that consist of four visually impaired players and a sighted goalkeeper and the field players wear eyeshades and rely only on the sound of a bell within the ball. As their sight is blocked, blind soccer players require physical and Audiospatial cognitive abilities. However, the sound source localization ability necessary for the audiospatial cognitive abilities utilized in this sport are not clear. Thus, this study aims to clarify the differences in sound source localization of visually impaired and sighted players.
METHODS: For the study, 18 players (age 21.8 years ± 3 years, height 171.2 ± 4.7 cm) with experience of playing blind soccer participated, and they consisted of a sighted group (10 people) and a visually impaired group (8 people). Each participant was seated on a chair, wearing an eyeshade, and their eye level was kept at 120cm. The participants had a switch that they were asked to press when they thought a rolled blind soccer ball reached a light sensor positioned near their feet. The ball was rolled toward the participants from four different directions (from the front [Front], from behind [Back], from right to left in front [Across the Front], and from right to left behind [Across the Back]). The speed of the ball (Speed) was random (1.0-9.0m/s), and the ball was rolled 13 times from each direction (total: 13 x 4). The time the ball reached the sensor and the time the switch was pressed were measured, and the values obtained were used to calculate errors (Reaction Error). The two groups were compared in terms of Speed and Reaction Error using a multiple regression analysis, with Reaction Error as the outcome variable and Speed and the two groups as the explanatory variables.
RESULTS: The results of the analysis were significant for all four directions: $F(2,186)=51.02$, $p<.001$ for Front, $F(2,189)=23.45$, $p<.001$ for Back, $F(2,191)=20.18$, $p<.001$ for Across the Front, and $F(2,194)=38.98$, $p<.001$ for Across the Back. The partial regression coefficients for Speed and the visually impaired group were significant in all cases, with the figures for Front being 0.06 and -0.14, respectively, for Back, 0.05 and -0.11, for Across the Front, 0.04 and -0.09, and for Across the Back, 0.06 and -0.11.
CONCLUSION: This study confirmed that the reaction of the sighted group tended to be slower (between -0.14 and -0.09 seconds) than the visually impaired group for all directions and as the speed of the ball increased. Studies have demonstrated that sound source localization abilities are developed through experience and training (Gibson, 2015). Based on these factors, the results suggested that visually impaired blind soccer players, through experience and training, have better sound source localization ability than sighted players.

GUIDELINES AND RECOMMENDATIONS TO EVALUATE A LOWER-LIMB PROSTHETIC DEVICE: A SYSTEMATIC REVIEW

GHILLEBERT, J., DE BOCK, S., FLYNN, L., GEEROMS, J., TASSIGNON, B., ROELANDS, B., LEFEBER, D., VANDERBORGHT, B., MEEUSEN, R., DE PAUW, K.

VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION:Evaluating the effectiveness of a lower-limb prosthetic device (LLPD) during daily activities is a crucial step in the iterative process of redesigning and product development of new generation prostheses. To date, several different experimental protocols have been applied to evaluate a LLPD in laboratory and field conditions, which causes study heterogeneity. Therefore, the aim of this systematic review was to formulate guidelines and recommendations in order to standardize the experimental methodology regarding the evaluation of a LLPD.
METHODS: Two databases, PubMed and Web of Science, were screened and studies published between 1997 and 2019 evaluating a LLPD were included.
RESULTS: Thirty-six articles were included. We identified forty-four outcome measures in four main categories: 54% were biomechanical, 25% physiological, 14% physical performance and 7% psychological. Seven eligible tests were identified: the two- and six-minute walk test (80%), slope walking (14%), stair climbing (8%), dual tasks (6%), timed up & go (3%) and balance tests (3%).
CONCLUSION: The main recommendation is to include functional tasks in a case-controlled (early stage) or crossover counterbalanced matched group study design (later stage). Biomechanical, physiological, physical performance and psychological outcome measures are key factors to investigate the human response to a LLPD in order to standardize experimental protocols.

Health and Fitness

THE ANALYSIS OF LINKS BETWEEN YOUNG SOCCER PLAYERS BODY COMPOSITION AND AGILITY

KOLTAI, M.1, NAGYVÁRADI, K.1, GUSZTAFIK, Á.1, SZEILER, B.1, HALASI, SZ.2
EÖTVÖS LORAND UNIVERSITY FACULTY OF EDUCATION AND PSYCHOLOGY

Introduction
Agility is the ability to move easily and quickly; it infers rapid onset, sudden stops and changes in direction. In modern football, this factor is considered the most important one in terms of efficiency. In the present research we were looking for answers to what body composition factors influence agility among junior soccer players.
Methods
U14, U16, U18 junior soccer teams of Topola Sport Club; N=66. Internationally standardized and recommended agility tests (Dribbling test, Illinois test, T-test). The movement structures of these tests perfectly model the solutions applied in the actual game. We used the Inbody 720 instrument measuring the body composition and Oxa Starter infrared timing gate instrument to measure speed agility tests.
The data have been processed with the IBM SPSS Statistics25 program ($p<0.05$).
Results
There is a moderate correlation between agility with a ball and without a ball (0.595). There is a moderate correlation between agility and body composition parameters: SMM, IWM, PM, MM (-0.453, -0.454, -0.453, -0.417) while the correlation between agility and Height, Weight, BMI, RLLM, LLLM, EWM is less than moderate (-0.318, -0.329, -0.276, -0.332, -0.330, -0.374). A slight correlation can be found between agility with a ball and body composition parameters. However, agility parameters and Body Fat Mass do not show any correlation.
Discussion
The impact of body composition on agility is lower than we expected.
In modern soccer, agility is an extremely complex skill, and the exact structure of its performance components is hard to define. The factors influencing players' agility should be emphasized and methodically developed in youth training in the light of future efficiency.

CHANGES OF PHYSIQUE IN PARTICULAR AGE GROUPS

NAGYVARADI, K., BIRÓNÉ ILICS, K., POLGÁR, T., LAKI, A., KÉRI, P., TÓTH, E., IHÁSZ, F.
EÖTVÖS LORAND UNIVERSITY

INTRODUCTION:The body composition is significantly changing as we age, however, the speed of such rate and changes is still uncertain. Some researchers may think that the main factor responsible for this change is the imbalance between the increased inactivity as we age and the growing energy intake. (UG. Kyle et al., 2001) Other researchers blame "sarcopenia" which is the loss of muscle mass) linked with the aging process. Losing muscle mass will change the basal metabolic rate, muscle strength and activity levels are decreasing and the energy level of elderly people will also decline. The goal of our research is to examine and study the differences of body compositions of certain age groups.
METHODS: Our samples are healthy local (city of Szombathely) adults between the ages of 18 and 83. The selection of our sample was described by the "snowball method". The studied individuals (N=402; average age 33, 9; 183 males, 219 females) are university students (full time and part time), active and retired people. The following data was added after the heath examination: height (BH/cm), fat-free mass (FFM/kg), body fat mass (BFM/kg), body weight (BW/kg), skeletal muscle mass (SMM/kg), percent body fat (PBF/%), waist-hip ratio (WHR), visceral fat area (VFA/cm2), obesity degree (%). The results of the studied individuals were automatically entered by the device called "Inbody 720". The data was analyzed by the Statistica 13.0 mathematical program package. We currently have the results of the inductive statistics available.
RESULTS: Based on the conductive statistic data, the following results are available given by our sample people participating in this research.
Their average height is 172,4cm, their average weight 72,1kg. Visceral fat area or belly fat is 71,1cm2 which is located at the abdominal area of the body. Their average waist-hip ratio (by genders) fall into the normal range of the specified field, 0, 87 for females and 0, 84 for males. This pretest shows that there is a significant connection between the age and the body weight (p 0,00), the age and the body height (p 0,00), the age and the percent body fat (p 0,00), the age and the visceral fat (p 0,00).
CONCLUSION: As our research indicates the body composition is changing with the aging process. The goal of our research is to introduce the rate of change in a certain age group. Finding the speed and the rate of this change will allow us to design a specific work out plan for different individuals and help them reach a fuller and better quality of life.

DEVELOPMENT OF HEALTH IN NEWER DIMENSIONS

POLGAR, T., NAGYVARADI, P., BIRÓNÉ ILICS, K., HURTIK, P., KOLTAI, M., IHÁSZ, F.
EÖTVÖS LORÁND UNIVERSITY

INTRODUCTION:There are many researches focusing on a chosen population's health issues in studies of Health Related Education. We often run into studies concentrating on the working class people both on a national and international level. These studies are assessing

the relationships between work and work environment and how these elements are affecting workers' health. Our main resource in this research was the "Ottawa Charta" (1986) with the emphasis on the actual environment. We are examining and monitoring the health status of the white color workers in our research.
METHODS: Our samples are local people of Szombathely who are white color workers. The companies and establishments as well as their workers were randomly selected by chance. The analyzed individuals in this research (N=71 people, average age 43, 6 years, 40 females and 31 males) are employed in different areas of the economy (national and international transportation, elementary and secondary education. The research was approved by the Research License 2018/427.
During the health examination, the following data was added: height (BH/cm), fat-free mass (FFM/kg), body fat mass (BFM/kg), body weight (BW/kg), skeleton muscle mass (SMM/kg), body mass index (BMI), percentage body fat (PBF %), waist-hip ratio (WHR), visceral fat (AVF/cm2), obesity degree (%). We used the applications of the Smart Watch called "Garmin" to constantly monitor the health status. After analyzing the starting status, we can create a health plan for the participant. The time span of the research is 6 months and we will have a checkup and control at 3 months. Currently, we only have the results of the starting status. The data was evaluated by the Statistica 13.0 mathematical program package.
RESULTS: We have the conductive statistics of the analyzed individuals available at the current time of this research. We can say, that the starting status of the participants in this research (N=71) are at an average height of 170, 2 cm and an average weight of 73, 0 kg. Their body mass index is 24, 9, which is about at the upper range of the normal level. The visceral fat or belly fat is an average of 94, 0 cm2 which is located at the abdominal part of the body. It is in the upper range of the normal level. Waist and hip ratio, by genders, fall into the normal range. Females at 0, 88 males at 0, 89
CONCLUSION: As a result of the continuous health monitoring provided by the smart lessons and the three-monthly control measurements, we expect an improvement in both body components, in particular visceral fat (VFA), and inactive lifestyle.

IMPACT OF SEDENTARY TIME ON CHRONIC KIDNEY DISEASE (CKD) AND DISABILITY INCIDENCE IN COMMUNITY-DWELLING JAPANESE OLDER ADULTS: A 4-YEAR PROSPECTIVE COHORT STUDY

LEE, S., BAE, S., HARADA, K., JUNG, S., MAKINO, K., SHIMADA, H.

NATIONAL CENTER FOR GERIATRICS AND GERONTOLOGY

INTRODUCTION:Patients with Chronic Kidney Disease (CKD) are profoundly weakened due to continuous atrophic and myopathic changes, and these changes could be caused by the sedentary lifestyle that is seen in patients with CKD. However, the relationship between CKD, longer sedentary time, and disability incidence is not clear. Thus, the purpose of this large-scale prospective cohort study of individuals who have non-dialysis CKD in Japan was to determine whether CKD with a longer sedentary time is associated with incident disability.
METHODS: This prospective cohort study sampled 5104 community-dwelling older adults (≥ 65 years) enrolled in a health promotion study in a general population. Among them, 4457 participants with no history of Parkinson's disease, dementia, stroke and living in the same city during the 4-year follow-up period at baseline were monitored for inclusion in the long-term care insurance (LTCI) system for 4 years, which was treated as the index of disability. This study used blood samples to assess estimated glomerular filtration rate (eGFR). Information on sedentary time was based on self-reported data collected using the International Physical Activity Questionnaire, which asks about daily time spent sitting over the previous 7 days. Cox proportional regression analysis was used to determine predictors of disability.
RESULTS: In total, 461 participants (10.3%) became newly certified as needing LTCI services. Cox regression models were adjusted for multiple confounders: eGFR < 45 mL/min/1.73 m2 (hazard ratio [HR] = 1.741; 95% confidence interval [CI] [1.193–2.539]) and eGFR < 45 mL/min/1.73 m2 with longer sedentary time (≥ 8 hours) (HR = 4.367; 95% CI [2.021–9.438]) remained significantly associated with disability incidence.
CONCLUSION: Our findings suggest that in the case of CKD, the disability incidence rate may be affected by sedentary time.

EVALUATING THE EFFICACY OF A GP LED PRE DIABETES INTERVENTION TARGETING LIFE-STYLE MODIFICATION

GREGORY, N., THATCHER, R.

ABERYSTWYTH UNIVERSITY

INTRODUCTION:Pre-diabetes is defined as a higher than normal blood glucose concentration and is associated with an increased risk of developing diabetes. In 2015, 182,600 people in Wales had diabetes while another 540,000 people, 21% of the adult population, were estimated to be at high risk of developing the disease. The North Ceredigion GP Cluster, which comprises seven GP practices and serves a population of 47,000, initiated a primary care led pre-diabetes intervention targeting patient education and lifestyle modification. The aim of this NHS service evaluation was to determine changes in health outcomes following intervention.
METHODS: Patients identified as at risk of diabetes (HbA1c between 42-47 mmol·mol-1) were invited to their registered medical practice for a 30-minute lifestyle consultation with a trained practice nurse. Measures for HbA1c, body mass index, waist circumference and blood pressure were collected prior to patients receiving information on the risks of diabetes and advice on healthy eating and physical exercise. Follow up appointments took place at 12- and 24-months post consultation during which baseline measures were repeated.
RESULTS: 592 patients completed baseline and 12-month follow-up testing, of which 292 also completed 24-month follow-up. For patients on whom two years of data were collected, BMI at 12-month (29.5±5.3) and 24-month (29.4±5.5) were both different from baseline (29.8±5.4, p=0.044) but were not different from each other. Waist circumference between baseline (99.8±13.1 cm) and 12-month (99.2±13.8 cm) did not differ but at 24-month (98.1±13.7 cm) it was lower than both baseline and 12-month (p<0.000). HbA1c fell from 43.9±1.6 mmol·mol-1 at baseline to 42.8±5.5 and 42.7±3.5 mmol·mol-1 at 12-month and 24-months, respectively, with the difference between baseline and 12-month and baseline and 24-month both reaching statistical significance (p<0.000); 12-month and 24-month values were not different. Of the 292 patients who attended an appointment after 24 months, 119 reverted to normal HbA1c values, 154 remained at risk and 19 had developed diabetes. For the 592 patients for which baseline and 12-month data were available significant differences occurred in BMI (29.9±5.6 to 29.8±5.8, p=0.003), waist circumference (101.9±13.9 cm to 101.2±14.3, p=0.013) and HbA1c (43.9±1.6 to 42.6±4.3 mmol·mol-1, p<0.000). At 24 months 217 of these patients had reverted to normal HbA1c values, 358 remained at risk, while 17 had progressed to diabetes.
CONCLUSION: The data suggest engagement with a primary care led 30-minute lifestyle intervention is beneficial in preventing the development of diabetes and in many cases, reverting back to normal blood glucose control. The lack of control group means cause and effect conclusions are not possible however the data does support the implementation of a randomised control trial.

CORRELATION BETWEEN HEART RATE RECOVERY AFTER MAXIMAL EXERCISE AND INSULIN RESISTANCE IN SEDENTARY OVERWEIGHT ADULT CHILEAN MEN: A PILOT STUDY

VON OETINGER, A., SADARANGANI, K., VILLANUEVA, S.

UNIVERSIDAD SAN SEBASTIAN & UNIVERSIDAD DE CHILE

INTRODUCTION:Attenuated heart rate recovery (HRR) after exercise has been demonstrated to be an independent predictor for mortality in healthy adults (1). Slower HRR following exercise has been linked to impaired glycemic and metabolic syndrome in young adults (2). The aim of this study was to analyze the correlation between the time to HRR and insulin resistance (IR) in sedentary overweight adult Chilean men.
METHODS: Ten voluntary overweight (BMI: 30.1 ± 0.8) sedentary male subjects, 30 to 39 years old (33.9 ± 0.9 years), were recruited for this pilot study. All subjects were free of any condition that would be relevant for the purposes of this research, such as diabetes, hypertension, cardiovascular disease and any other pathology that may affect their metabolic response to exercise.
The oxygen peak consumption (VO2 peak) was evaluated for all the subjects using an ergospirometer. Heart rate was recorded by a heart rate monitor from 15 minutes before the exercise session to 50 minutes after the evaluation of VO2 peak. We recorded the time when the subject reached their rest heart rate after exercise to obtain the HRR. IR was defined if homeostasis model assessment (HOMA-IR) was ≥ 2.6.
VO2 peak was 31.41 ± 2.22 ml·kg-1·min-1. Anthropometric characteristics such as body mass index (30.1 ± 0.8 kg/m2), fat percentage (29.1 ± 1.4 %) and waist circumference (99.3 ± 11.71 cm) were measured. Blood tests were measured in fasting state: glycaemia (85 ± 3 mg/dl), insulin resistance (HOMA) 2.44 ± 0.28 and lipidic profile (total cholesterol 210 ± 13 mg/dl, HDL 45 ± 5 mg/dl, VLDL 38 ± 5 mg/dl, LDL127 ± 12 mg/dl and triglycerides 190 ± 23 mg/dl). Variables were analyzed by the Spearman correlation analysis.
RESULTS: The HRR was correlated positively to HOMA ($r = 0.86$, $p < 0.001$), insulinemia ($r = 0.71$, $p < 0.001$) and glycaemia ($r = 0.87$, $p < 0.001$). Amongst the other measured variables only waist circumference ($r = 0.85$, $p < 0.001$), total cholesterol ($r = 0.83$, $p < 0.001$) and LDL ($r = 0.67$, $p < 0.001$) were positively correlated with HRR.
CONCLUSION: Our findings in overweight adult Chilean men support and extend previous studies examining associations of HRR with IR. According to Kuo et al (3), insulin resistance was inversely associated with HRR in healthy adolescents and adults. It is clinically important to investigate the nature of the link between the HRR and metabolic disorders.

CORRELATIONS BETWEEN SEDENTARY BEHAVIOR ON WORKDAYS AND DURING WORK HOURS AND PHYSICAL ACTIVITY LEVEL AND OBESITY IN JAPANESE WORKERS

JIAMENG, M.

SENDAI UNIVERSITY

INTRODUCTION:
Reducing sedentary behavior (SB) and increasing lifestyle activities, including light, moderate, and vigorous physical activities, may be an option to prevent metabolic syndrome. However, objective data on physical activity level and obesity index are limited for SB in terms of specific times of the day. The purpose of this study is to utilize objective methods to determine relationships between SB on workdays and during work hours- with physical activity levels and obesity indices.
METHODS: We evaluated SB and physical activity levels using a triaxial accelerometer on working days during work hours (9 am-6 pm) in 110 Japanese workers. Metabolic equivalents (METS) were used to categorize, in terms of physical intensity, the minutes of sedentary time (≤1.5 METS) and physical activity. Physical activity intensity was divided into light physical activity (LPA, 1.6-2.9 METS), moderate physical activity (MPA, 3.0-5.9 METS), and vigorous physical activity (VPA, ≥6.0 METS), as well as total physical activity level measured per hour (METS/hour). The relationship between number of workdays, SB during work hours with each physical activity level, number of steps taken, and obesity indices were analyzed using the partial correlation method.
RESULTS:
The study presents the partial correlation coefficients for SB, physical activity level and obesity; with adjustments for social demographic variables made. On workdays, MPA ($p < 0.001$), VPA ($p<0.001$), and METS·hour ($p<0.001$) were shorter in proportion to longer SB and fewer steps during work ($p<0.016$), and lower muscle mass. Longer SB time during work was associated with shorter LPA ($p<0.037$), MPA ($p<0.025$), VPA ($p<0.048$), and METS·hour ($p<0.007$), and fewer steps taken during work ($p<0.029$).
CONCLUSION:
We found that there is a negative correlation between LPA and SB during work hours. This result appeared to be due to a longer duration of time-spent standing rather than working while seated. The results of our study suggest that the effect of SB on muscle mass on the workday is reduced through increased walking during work hours and commuting, as well as during free activity in times spent outside of work. All of this could be useful for reducing SB during workdays.

EFFECTS OF A MULTI-COMPONENT EXERCISE PROGRAM IN THE SELF-PERCEPTION OF HEALTH AND THE AFFECTIVE CONDITION OF INSTITUTIONALIZED OLDER ADULTS

UGARTEMENDIA, M., ZINKUNEGI, N., ELORDI, U., CALVO, J.J., MENDILUCE, N., VIRGALA, J., ZARRAZQUIN, I., IRAZUSTA, A., KORTAJARENA, M.

UNIVERSITY OF THE BASQUE COUNTRY-UPV/EHU

INTRODUCTION:Many studies show that physical exercise promotes psycho-affective well-being in elder people and improves the self-perception of health. Physical inactivity related to aging tends to develop cognitive deterioration and depression. So the performance of

regular physical exercise is an effective way to prevent depression. The aim of this study was to examine the changes caused by a multi-component exercise program in the perception of health and in the affective condition of institutionalized elder people.
METHODS: The participants were 38 institutionalized older adults (age 80.2 + 7.65) from the Zorroaga Residence in San Sebastian (Spain) who were randomized into two groups: Control and Intervention (multi-component exercise sessions, three days a week for 3 months). The inclusion criteria were ≥ 65 years, Barthel index> 60, Mini Mental State Examination > 14 and do not present no unstable medical conditions that impeded physical activity. Before and after the intervention program, we recorded the quality of life related to health through SF-36 and the affective state through the Geriatric Depression Scale (GDS). We analyzed if there were statistically significant differences between the Control and Intervention group by means of the t test or Wilcoxon for paired samples.
RESULTS: After the multicomponent exercise program, the intervention group significantly improved in the self-perception of health ($p < 0.05$), specifically in the sections related to physical health. While the control group improved significantly in the social section ($p < 0.05$). Likewise, the intervention group improved significantly in the affective state ($p < 0.05$), that is, the GDS score improved, while the control group did not show significant changes.
CONCLUSION: Other studies carried out in institutionalized elder people, in addition to observing improvement in the health perception of the intervention group, the control group worsened significantly after the multicomponent exercise program. Regarding the affective state, there are studies that have obtained a better GDS score, while in others there has been no significant improvement. This leads us to believe that the affective state could be related to other uncontrolled factors. Additional studies are needed to better understand the effects of a multicomponent exercise program on the perception of health and to determine the factors related to the affective state of institutionalized older adults.

HEMATOLOGICAL AND PHYSIOLOGICAL PARAMETERS IN PHYSICALLY ACTIVE BOYS AND GIRLS

PLUNCEVIC GLIGOROSKA, J., DEJANOVA, B., EFREMOVSKA, L.J., MANCEVSKA, S., PETROVSKA, S.
MEDICAL FACULTY, UNIVERSITY SS CYRIL AND METHODY, SKOPJE

INTRODUCTION:The primary need during physical activity is to supply active tissues with energy source and oxygen. The cardio-physiological and hematological parameters are measurements of two main systems (cardiovascular and blood) that provide this need. The purpose of this paper was to investigate the red blood cell parameters and cardio-physiological indicators in children age span from 10 to 12 year, regarding the sex differences.
METHODS: We studied 99 children which regularly participate in different sport activities divided in two groups by gender, age span 10-12 years (mean age, girls = 10.61 •0.5 years; boys = 10.54 •0.5). The mean time of participation in sport were 2.91 (1.63) years averagely 3.07 hours weekly for girls and 3.46 (1.8) years and 3.69 hours weekly for boys. Red blood count (RBC), hemoglobin (Hb), hematocrit (Hct), mean corpuscular volume (MCV), mean corpuscular hemoglobin concentration (MCHC), mean hemoglobin concentration (MCH) were analyzed in standardized capillary blood samples. Submaximal ergometrical test by Bruce was used to determine maximal oxygen consumption (VO2 max), exercise time (ET) and heart rate before testing (HRR).
RESULTS: Descriptive statistics for investigated parameters for girls (N=25) versus boys (N=74) was as follows: RBC = 4.96 (0.34) vs 4.86 (035)*1012/l; Hb = 12.9 (0.96) vs 13.09 (0.97) gr/dl; Hct = 42.271 (2.32) vs 41.19 (2.68); MCV=85.52 (5.86) vs 85.28 (3.63); VO2 max= 28.33 (5.81) vs 42.31 (4.95) ml/kg/min; HRR= 96.5 (12.16) vs 80.86 (11.67) bpm.
CONCLUSION: The girls and boys which are physically active showed normal value of hematological parameters. Regarding the sex all hematological parameters were insignificantly different. Concerning the results of cardiovascular testing girls showed significantly higher heart rate at rest and significantly lower exercise time and VO2 max. At this pre-pubertal age, in our investigated sample boys and girls show no difference in red blood cell variables, but the boys showed significantly better parameters of ergometry test, which could be a result of longer and better physical conditioning.

THE RELATIONSHIP BETWEEN PHYSICAL FITNESS AND ACADEMIC PERFORMANCE AMONG STUDENTS AT A LARGE UNIVERSITY IN CHINA

WU, C.T.1, LI, X.2, XIE, R.2, PENG, X.2, GUO, L.3,4, ROCHESTER, C.A.5, HUNG, T.M.6
UNIVERSITY OF SOUTH CAROLINA UPSTATE

INTRODUCTION:An emerging body of evidence has revealed a positive relationship between physical fitness and academic achievement in school aged children. However, few studies with college students have examined this relationship. The purpose of the current study aimed to assess various fitness data in college students using the Chinese National Student Physical Fitness Standards (CNSPFS) battery to investigate this relationship between physical fitness and academic performance in college students. We hypothesized; 1) physical fitness indicator related to cardiorespiratory endurance (i.e., 1000- and 800-meter run) would be positively correlated with academic performance and; 2) other physical indicators from CNSPFS data-set would be positively correlated with academic performance.
METHODS: A secondary analysis of data collected by Office of Institutional Effectiveness and the Department of Sports at the University of Electronic Science and Technology of China on sophomores (n = 3799; aged 19.64 ± 0.80; 16 % females) from the year during 2014 to 2017 in Sichuan province, China was conducted. All participants completed a standardized achievement test on five study subjects (i.e., College Physics, Probability and Statistics, General English, Calculus, Linear Algebra and Geometry). Physical fitness was assessed using the revised 2014 version of the CNSPFS, which involves a total of 7 fitness indicators. Each fitness indicator score was weighted by an age- and sex-specific percentage. Analyses were conducted using a one-way ANOVA for each academic group (AB, C, DF) to determine whether there were statistically significantly differences between groups among the 7 CNSPFS fitness indicators including BMI, Vital capacity of lung, 50 m sprint, sit and reach, standing long jump, timed sit-ups/pull-ups (sex-specific), and 1000/800 m run (sex specific).
RESULTS: Relative to their counterparts, students who were higher in academic performance exhibited better fitness level in cardiorespiratory endurance (group C versus DF, $p < .05$), leg strength (group AB versus DF, $p < .001$; group C versus DF, $p < .005$), and flexibility (group AB versus DF, $p = .004$; group C versus DF, $p = .004$). No such difference was observed in other fitness measures.
CONCLUSION: The positive relationship between physical fitness and academic performance might provide a rationale for further investigating the case and effect of exercise engagement on university students' academic performance using a randomized controlled trial. In addition, the selective relationship between fitness measures (i.e., leg strength, flexibility and cardiovascular endurance) and academic performance is important for future inventions regarding university student exercise involvement.

THE RELATIONSHIP BETWEEN OBJECTIVELY MEASURED PHYSICAL ACTIVITY AND QUALITY OF LIFE AMONG SCHOOL-AGED CHILDREN

OKAZAKI, K.1, KOYAMA, Y.2, OHKAWARA, K.3

1: TOHOKU GAKUIN UNIVERSITY , 2: SEIKEI SENIOR HIGH SCHOOL , 3: UNIVERSITY OF ELECTRO-COMMUNICATIONS

INTRODUCTION:Little is known about the relationship between health-related quality of life (HRQOL) and objectively measured physical activity (PA) among school-aged children (Wu et al, 2017). This study aimed to investigate the relationship between HRQOL and objectively measured moderate-to-vigorous PA (MVPA), light PA (LPA), and sedentary behaviour (SB) among children.
METHODS: A total of 372 children (180 boys and 192 girls) from the fourth to sixth grade were asked to complete a questionnaire and wear a triaxial accelerometer for more than seven consecutive days. The Japanese version of the Pediatric Quality of Life Inventory (PedsQL; Kobayashi et al., 2010) was used to assess HRQOL. The minimum amount of accelerometer data was 3 days with at least 10 waking hours of wear time per day, including at least one weekend day. Ordinal logistic regression analysis with a generalized linear model adjusted for sex and grade was performed to examine the relationships. The PedsQL data (dependent variable) were converted into three categorical variables (good, medium, and poor status) according to the mean and standard deviation (SD) of the data. The accelerometer data (independent variables) were also converted into categorical variables.
RESULTS: The mean (SD) total, physical health, and psychosocial health scores on the PedsQL were 86.7 (9.8), 88.6 (11.4), and 85.7 (10.7), respectively. The mean (SD) min/day of objectively measured MVPA, SB, and LPA were 69.2 (26.3), 453.5 (89.2), and 321.3 (56.6), respectively. Engaging in high (≥90 min/day, odds ratio [OR]=2.6, 95% confidence interval [CI]=1.1–5.9), somewhat high (60–89 min/day, OR=2.0, 95% CI=1.0–4.0), and somewhat low (45–59 min/day, OR=2.2, 95% CI=1.1–4.7) levels of MVPA was significantly related to good psychosocial health status compared to a low (<45 min/day, OR=reference) level of MVPA. Further, engaging in a high (≥377 min/day, OR=2.9, 95% CI=1.1–7.6) level of LPA was significantly related to good psychosocial health status compared to a low (<255 min/day, OR=reference) level of LPA.
CONCLUSION: Our findings suggest that a high level of MVPA and LPA is associated with good psychosocial health status among children. However, there were no statistically significant relationships between HRQOL and SB levels. Children who engaged in less than 45 min/day of MVPA had a poorer HRQOL among those who did not meet the current MVPA guideline of 60 min/day. Increasing LPA may be one of the health promotion options for children who do not have a physically active lifestyle.

PERIODIZATION PRINCIPLES IN THE REHABILITATION OF MULTIPLE SCLEROSIS

KEYTSMAN, C.

HASSELT UNIVERSITY

INTRODUCTION:In high-performance sports settings, training programs are not based on single progressive linear training stimuli for a prolonged period but are divided in periodically alternating blocks of 1-6 weeks and involve varying exercise modalities (intensity, duration, frequency) and periods of rest/recovery. Rehabilitation programs in various populations however still often use continuous linear progression models with single stimuli and training modalities, resulting in suboptimal training/rehabilitation. Recently, we explored adherence to a periodized cycling program in mildly-affected relatively fit MS patients (Keytsman et al. 2018 MSARD), with e.g. promising effects on exercise capacity (VO2max +5%, workload +11%). We now evaluate such a periodized exercise program in this population compared to a more conventional, linear progressive training/rehabilitation program.
METHODS: This abstract presents preliminary data originating from on ongoing study, where exercise capacity (maximal graded exercise test: VO2max, workloadmax, time until exhaustion) was assessed at baseline (PRE). Hereafter, MS patients were randomized into a conventional (CLA, n = 7) or a newly developed periodized (PER, n = 7) exercise intervention (12w). Classic, moderate intensity endurance training (60-80% HRmax, 5 training sessions/2w, 60min/session) was performed on a stationary bicycle. Periodized exercise included 4 recurrent 3-week cycles of moderate endurance training (week 1, 3 sessions, 60min/session, 60-80% HRmax), high intensity interval training (week 2, 3 sessions, 10min/session; 3x20sec supramaximal sprint interspersed with recovery intervals of 2min), and recovery weeks (week 3, 1 high intense interval session as described above). Hereafter, POST measurements were performed similar to PRE. Total exercise volume of both programs was calculated using a previously published formulae (weeks*session/week*min/session*%HRpeak, Hansen et al. 2018 Eur J Prev Cardiol) and expressed as total peak-effort training hours.
RESULTS: Twelve weeks PER training significantly improved VO2max (+15%, p=0.03), workloadmax (+21%, p=0.002) and time until exhaustion (+25%, p=0.03). CLA improved workloadmax (+17%, p=0.001) and time until exhaustion (+17%, p=0.004) significantly, but not VO2max (+8%, p=0.12). Pre-post differences between PER and CLA for VO2max (p=0.53), workloadmax (0.394) and time until exhaustion (p=0.17) did not differ. For CLA, total exercise volume included 1728 total peak-effort training hours, whereas PER included only 736.
CONCLUSION: This preliminary data shows that despite substantially lower training time (57% less peak-effort training hours), 12 weeks of periodized exercise training in Multiple Sclerosis patients induced at least similar improvements in parameters of exercise capacity compared to classic endurance training.

THE EFFECT OF REGULAR DANCE TIME ON PHYSICAL FITNESS IN JAPANESE PRESCHOOL CHILDREN

KUNO-MIZUMURA, M., KAWANO, Y., SHIONOYA, Y., YOSHIDA, M.

OCHANOMIZU UNIVERSITY

INTRODUCTION:Nowadays, high level of inactivity and sedentary lifestyle has spread out for all-ages including small children. In Japan, the Ministry of Education and Science has proposed to increase physical activity for preschool children using their guidelines and the handouts for teachers and parents. To increase physical activity level in preschool children, play time at kindergarten would be one of options. However, for preschool children, there are less information about the effect of regular exercise during playtime based on the evidence from interventional study. Many previous studies had investigated that dance would be the effective physical activity to enhance cognitive function especially elderly people because of multiple tasks during dancing. For preschool children who might be under devel-

opment of neural functions, dance would be one of the recommended exercises during their play time. So the purpose of this study was to investigate the effect of regular dance time at kindergarten to physical fitness in Japanese preschool children.
METHODS: Subjects were seventy-four preschool children aged 5-6 years old living in Tokyo. Fifty-three of them (24 boys, 29 girls) completed regular dance time intervention for one month. Rest twenty-one children (9 boys, 12 girls) completed the same intervention for four months. Physical fitness measures were evaluated by the battery tests for preschool children in Japan such as the performance of standing long jump, 25m run, throwing the soft ball, catching the ball, repetitive small jumps, sustaining the balance with their both arms and sit-and-reach test both before and after the dance intervention. We had designed three different types of 5-minutes dance video program for preschool children. We also asked their nursery teachers to use one of these dance videos for the demonstration at kindergarten every day. Subjects danced with this video program twice a day for either one or four months at kindergarten.
RESULTS: Only after 4months intervention, significant improvement were obtained in catching ability, throwing ability, agility evaluated by repetitive small jumps, and sit-and-reach test measures, while there was no significant difference in running and jumping performance, For 1month intervention group, there was no significant change in physical fitness measures.
CONCLUSION: From the results of this study, it is indicated that four-month dance intervention would be effective to improve motor skills in preschool children. Dance would be favorable exercise even for preschool children to enhance motor skills.

EFFECTS OF RURAL COMMUNITY-BASED INTEGRATED HEALTH EDUCATION AND EXERCISE INTERVENTION TO PROMOTE HEALTH IN ELDERLY WOMEN WITH KNEE OSTEOARTHRITIS

OH, S.L.1, KIM, D.Y.1, BAE, J.H.1, KIM, B.R.1, LEE, J.Y.1, LEE, S.H.1, KIM, H.J.1, MOON, K.H.2, KIM, H.J.2, LIM, J.Y.1,3

1: SEOUL NATIONAL UNIVERSITY BUNDANG HOSPITAL, 2: HEALTH & LONGEVITY RESEARCH INSTITUTE IN SUNCHANG COUNTY, 3: INSTITUTE ON AGING IN SEOUL NATIONAL UNIVERSITY

INTRODUCTION:Osteoarthritis (OA) of the knee is a major cause of pain and locomotive disability and is highly prevalent in the elderly population worldwide, especially in rural regions where physical demands are high. The purpose of this study was to examine the effect of rural community-based integrated health education and a resistance exercise-based intervention program to promote health in older adults with OA.
METHODS: Participants were assigned in the control (OA-Con, n=20) and intervention (OA-Ex, n=40) group. All participants underwent a muscle function assessment and questionnaire evaluation before and 5 months after the interventions. The OA-Con group participated in the health education program led by a multidisciplinary group, and the OA-Ex group performed exercise training together with participation in the health educational program for 5 months. The primary outcomes measured muscle function using a timed chair stand (TCS) test, timed up & go (TUG) and knee extensor strength tests, and the WOMAC score. We measured body composition and conducted questionnaire evaluations (SARC-F scale and SOF index) as the secondary outcomes.
RESULTS: Of sixty participants who were enrolled in this study, 32 (11 OA-Con, 21 OA-Ex) provided follow-up data at baseline and after 5 months. In the OA-Con group, TCS (p=0.003) and TUG (p=0.005) were significantly increased compared to pre-test, but in the OA-EX group, TCS was significantly decreased (p<0.001, 36.38%) and TUG tended to decrease after 5 months of intervention. The OA-Ex group showed significant improvement in knee extensor strength after 5 months of intervention compared to pre-test (p=0.003). In contrast, the OA-Con group exhibited a decreased knee extensor strength after the 5 months compared to baseline (p=0.011). The OA-Ex group showed that, among the WOMAC scores, the pain and stiffness subscores were unchanged during the 5 months, but in the OA-Con group, these subscores increased significantly during the 5 months (p=0.007, 54.87%, and p=0.026, 85.84%, respectively). For sarcopenia diagnoses using the SARC-F scale, the OA-Con group showed a two-fold increase in the number of older adults with sarcopenia (p=0.043), whereas the OA-Ex group showed a 37.5% decrease.
CONCLUSION: These results suggest that an integrated intervention program combining self-directed, home-based exercise training with health education is effective for promoting health in older adults with knee OA in rural areas. In addition, this study could provide a community-academic-clinical integration model as an intervention strategy based on the rural area for elderly health promotion.

CLINICAL AND AMBULATORY BLOOD PRESSURE RESPONSES AFTER DIFFERENT INTENSITY OF ACUTE RESISTANCE EXERCISE

CHU, C.H.1, MA, K.C.1, TSAI, C.L.2, CHEN, F.C.1, PAN, C.Y.1, CHEN, P.L.1, HUANG, C.Y.1

1: NATIONAL KAOHSIUNG NORMAL UNIVERSITY , 2: NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION:Acute resistance exercise (RE) can reduce the blood pressure (BP) of hypertensive subjects (Jones, et al., 2007); however, the healthful effects of RE depend on the ideal combination of many variables. The aim of this study was to evaluate the effect of different intensity of acute RE on the clinical BP (CBP) and ambulatory BP (ABP) of individuals with pre-hypertension and hypertension.
METHODS: Fourteen subjects (44.93 ± 10.31 years) with a previous diagnosis of pre-hypertension and hypertension gave written consent to take part in the study. All subjects underwent, in a random order, three experimental sessions: non-exercise control (C, 40 minutes of rest), low-intensity RE (L-RE, 40% 1RM, 3 sets of 15 repetitions of the 8 exercises), and moderate-intensity RE (M-RE, 60% 1RM, 3 sets of 10 repetitions of the 8 exercises). Heart rate (HR) and BP were measured before and after each session (every 15 minutes during 60 minutes) using both a mercury sphygmomanometer and a oscillometric methods (Cardio Vision○R Model MS-2000). Then, they took a shower and ABP monitoring (SpaceLabs model 90217) was performed. The results were analyzed by two-way repeated measures ANOVAs and one-way ANOVAs.
RESULTS: The main findings were that (a) L-RE decreased clinical systolic BP (-7.87 ± 4.12 mmHg, $p < .05$) and rate pressure product (RPP) (-1378 ± 35 mmHg × bpm, $p < .05$) during the first 60 minutes, and both M-RE and C observed no differences, (b) for the 24-hour ABP, the systolic BP ($F = 4.475$, $p < .05$) and diastolic BP ($F = 3.544$, $p < .05$) were reduced after L-RE session and sustained for 5 hours, and (c) the mean 24-hours, daytime, and night BP were not significantly different among three experimental sessions.
CONCLUSION: The present study demonstrated that a single bout of L-RE promoted post-exercise hypotension in the laboratory, and this response was sustained when subjects returned to their activities of daily living. Our findings suggest a potentially positive health benefit of RE. The protocol was shown to be safe, and it can help the prescription of the first session of exercise to pre-hypertensive and hypertensive individuals by professionals.

EFFECTS OF VIDEO VIEWING NOT AIMED AT MOTIVATING EXERCISE DURING ERGOMETER EXERCISE ON VOLUNTARY EXERCISE DURATION

SHIMIZU, S., NAGASHIMA, M., OKADA, K., SUZUKI, M., ANDO, S., OHKAWARA, K.

THE UNIVERSITY OF ELECTRO-COMMUNICATIONS

INTRODUCTION:The use of video-assisted exercise may be a potential modality to prevent lifestyle diseases. Many present researches use videos to make exercise enjoyable. However, Tremblay et al. reported that the use of activities for entertainment purposes can secure a higher amount of physical activity than that of intentionally urged activities. Therefore, we presumed that an approach to increase the amount of physical activity by eliminating exercise consciousness would be effective. This study examined the effect of video viewing not aimed at promoting the motivation to exercise using flat-panel display and head mounted display (HMD).
METHODS: Ten healthy males in their 20s participated. Following physical assessments, each subject performed in the following pattern of cycling exercises: (A) video viewing by flat-panel display, (B) viewing by HMD, and (C) no viewing. We used a documentary video of animals because there was no association with exercise, the elapsed time could not be deduced from the image, and it was not easily affected by personal preference. We recorded the start and end times of the exercise (maximum: 45 min per trial). We also measured the heart rate at rest and exercise, RPE (Borg scale), and emotional state using 3 question papers.
RESULTS: Compared to trial C (938 ± 447 s), the exercise time during trial A (1207 ± 550 s) increased significantly. Although trial B (1206 ± 485 s) did not show significant difference from trial C, it showed an increasing trend (moderate effect size: $\eta p2 = 0.067$). There was no change in the emotional state before and after exercise. However, in the analysis by effect size, When Trial B, comfort did not increase significantly ($\eta p2 = 0.111$) and anxiety did not decrease significantly ($\eta p2 = 0.122$).
CONCLUSION: The exercise time increased by video viewing. However, the hypothesis that strong immersion from using HMD increases exercise time was rejected. After the exercise, some subjects reported that experienced heat or heaviness due to wearing the HMD. Therefore, the HMD we used could be inadequate with respect to comfort during exercise. Further studies are needed to compare video viewing that not aimed at motivating with viewing aimed motivating to exercise.

COMPARISON OF BALANCE ABILITY AND MUSCULAR STRENGTH OF THE LOWER EXTREMITY BETWEEN DIFFERENT GENDERS- A CASE STUDY FOR CHIAYI COUNTY

CAI, M.C., LIN, C.F., CHUNG, Y.K., WANG, H.H., LI, S.F.

NATIONAL CHUNG CHENG UNIVERSITY DEPARTMENT OF ATHLETIC SPORTS (MASTER PROGRAM IN SPORT AND LEISURE EDUCATION)

INTRODUCTION:At present, the death of accidental injuries is the sixth highest among the deaths of Taiwanese people. The deaths caused by falls account for about 21.4% (1). Taiwan has entered an aged society, in the face of degeneration of sensory systems in the elderly and the decline in fitness and balance, the appropriate fall risk assessment is important for fall prevention interventions. In this study, the assessment of the balance of senior citizens was conducted by gender grouping to understand the current fitness status and balance ability of senior citizens in Chiayi County.
METHODS: This study was conducted on 60 healthy elderly people aged 65 years or older in Chiayi County. The subjects were 30 males and females. The average age of males was 71.97±3.85 years old, the height was 165.67±5.12 cm, and the body weight was 65.83±9.80 kg. The average age of females was 71.17±3.53 years old, the height was 154.17±5.45 cm, and the weight was 57.93. ±9.10 kg. Before the test, Subject must fill out the basic data questionnaire, the experimental consent form, and have the 2.44 meters up-and-go test and 30s chair-stand test in the functional fitness, and use the WIIFIT balance board with Clinical Test of Sensory Integration and Balance(CTSIB) to detect the static balance ability.
RESULTS: In order to understand whether gender is different in balance ability, this study used Independent Sample t test to determine the difference in detection. In terms of basic physiological parameters, male height and weight were significantly higher than females($P<.005$), and the 2.44 meters up-and-go test and 30-second sit-up test was also significantly higher than female($P<.005$). In the open-eye soft-table project, there was no significant difference between the male SI value of 1.07 and the female SI value of 1.15. In the closed-eye soft-table project, the male SI value was 1.68, and the female SI value was 1.94, which was significantly lower than that of the female study($P<.005$). The results showed that the SI values of male open and closed eyes were lower than those of females, but only the SI values of closed eyes were significant. Men were significantly better than females in the two tests of functional fitness, indicating why men were higher than females in closed-eye SI values.
CONCLUSION: This study estimates that men are better than women in terms of closed-eye balance because of their muscle fitness. Therefore, we hope that in the future, we can design training suitable for different genders to improve the self-exercise and health management ability of senior citizens. The balance of seniors reduces their risk of falling.

THE RELATIONSHIP BETWEEN MUSCLE STRENGTH AND PREVALENCE OF METABOLIC SYNDROME: A CROSS-SECTIONAL STUDY AMONG JAPANESE MEN

MIYAMOTO, R.

KAMEDA MEDICAL CENTER

INTRODUCTION:Some papers have reported that there is an inverse relationship between muscle strength and the prevalence of Metabolic Syndrome. However, the data is limited to apply this relationship among Japanese. The purpose of this study is to investigate the relationship between muscle strength measured by a very simple one-leg-stand-up test (from a 40cm high seat) and the prevalence of Metabolic Syndrome among Japanese men.
METHODS: This cross-sectional analysis was conducted in 1,653 Japanese men [median (inter quartile range) age 61 (55-67) years] who completed health examinations and a one-leg-stand-up test. Smoking, drinking, and physical activity habits were collected through a self-administered questionnaire. The prevalence of Metabolic Syndrome, based on the standard by Japan Society for the Study of Obesity

(JASSO) targeted to Japanese, was evaluated. Odds ratios and 95% confidence intervals for the prevalence of diabetes were obtained using logistic regression models to assess the relationship between muscle strength and the prevalence of Metabolic Syndrome.
RESULTS: In total, 64 participants had Metabolic Syndrome, and 476 participants could not stand-up from a 40cm high seat with one leg (non-stand-up group). Using the non-stand-up group as reference, the age-adjusted odds ratio of the stand-up group was 0.50 (0.30-0.86). After adjustment for age, body mass index, smoking, drinking, and physical activity, the multivariable odds ratio was 0.56 (0.33-0.96).
CONCLUSION: The findings indicate that low muscle strength measured by a very simple fitness test would be associated with a higher prevalence of Metabolic Syndrome among Japanese men, although its correlation was attenuated after adjusting for confounding factors.

PHYSICAL ACTIVITY LEVELS AND FRAILTY IN PORTUGUESE COMMUNITY-DWELLING OLDER ADULTS – A CROSS-SECTIONAL STUDY

CARVALHO, J., WEEGE, M., BARROS, D.
UNIVERSITY OF PORTO

INTRODUCTION:Frailty is an emerging prevalent syndrome among older adults. It is described in literature as a geriatric condition characterized by age-related physiological declines that result in increased vulnerability to negative health outcomes. Aging itself presents as the main etiologic factor. Lifestyle, however, also seems to play a major role in frailty development. In this sense, physical activity (PA) may be considered a crucial element not just as preventive tool but as an interventional method in frailty onset and progression. Yet, despite the highly broadcasted benefits of PA, the overwhelming majority of older people in Portugal do not meet the minimum recommended PA levels needed to maintain or improve health. Purpose: To compare PA levels between robust, pre-frail and frail elderly people and verify the proportion of individuals who did not meet PA recommendations.
METHODS: The final sample consisted of 105 community-dwelling older adults (mean age=73,3± 5,8 yrs; 62 women); physical frailty was assessed by Fried's five criteria and PA was objectively measured by accelerometry. One-way ANOVAs and Krukal-Wallis tests were used to analyze, respectively, PA levels and the proportion of individuals who did not meet recommendations in the different categories of frailty.
RESULTS: i) overall, 52,4% (n=55) of the sample did not meet weekly moderate-to-vigorous physical activity (MVPA) recommendations and, on average, engaged in 7.8 hours of sedentary behavior daily; ii) between frailty categories, there were no significant differences in the sedentary and light PA; iii) the frail elderly presented reduced MVPA (0.1h / day), which was significantly different from the other groups ($p < 0.001$); iv) 90.9% of the frail, 63.8% of the pre-frail and 22.2% of the robust elders did not comply with the recommendations; these differences were significant among the groups ($p < 0.001$).
CONCLUSION: Portuguese older adults present high levels of sedentary behavior. Moreover, MVPA seems to be an important influence in the frailty syndrome since frail elderly present lower values compared to pre-frail and robust. Although these findings provide relevant insights concerning the importance of PA in frailty of community-dwelling older adults, additional evidence is needed to validate and build upon our findings using a larger and more representative sample.

CHANGES IN THE LIPID PROFILE OF OBESE CHILDREN AFTER A SUMMER CAMP

LIMA, H., RAUBER, S., MELO, G., SILVA, I., RAMOS, I., SILVA, A., CAMPBELL, C.
UDF-CENTRO UNIVERSITÁRIO

INTRODUCTION:Obesity has been regarded a world health public problem being related to either social, physical, emotional and physiological impairment. The most cases of obesity are linked to a bad nutritional habits and physical inactivity, the prevalence in Brazil shows that 60% of the population are classified as overweight or obese. Therefore, prevention, especially in childhood is paramount in order to avoid metabolic disorders, and consequently the risk of chronic diseases, namely changes in glucose metabolism, a factor that presents high evidence in obese individuals. The recreational intervention strategy with multidisciplinary teams has been reported in the literature as one of the most effective methods in the treatment and obesity control, in special summer Health Camps with recreational physical activity in immersion model in an active lifestyle (e.g. games, sport). Nevertheless, most of these camps do not have scientific purpose and a clear set of goals linked to lipid profile. Consequently we investigated the changes in the lipid profile of obese children after educational and recreational health camps (KIDS).
METHODS: The model of (KIDS) with seven days of interdisciplinary intervention was attended by twenty-one children (9 boys and 12 girls, 10.1 ± 1.2 yrs). To evaluate nutritional education, emotional management, physical activity practice and sleep care the lipid profile (total cholesterol, HDL and LDL) (before and after summer camp) (KIDS) there were necessary two days parents engagement (one weekend) and seven days children engagement. The focus of summer camp KIDS was to promote educational and motivational activities to improve motor skills, movement knowledge, nutritional guidelines, social, personal skills to achieve healthy lifestyle. It was performed a paired T-test for the comparative baseline post-camp and effect size using Cohens.
RESULTS: total cholesterol values was decreased (161.15 ± 32.45 pre and 130.74 ± 21.00 post, effect size = 1.023), regarding triglyceride values it was observed a significant improvement (130.32 ± 96.01 pre and 50.05 ± 19.86 post, size of the effect = 1.385), the HDL values had a small increase, not very significantly (46.79 ± 11.50 pre and 48.42 ± 10.30 post, effect size = -0.149), whereas the LDH showed a significant decrease (93.22 ± 26.37 pre and 69.89 ± 21.99, effect size = 0.964).
CONCLUSION: From the current results, the lipid profile after seven days of KIDS had significant changes, showing reduction in total cholesterol, triglycerides and LDL. These results may suggest that a recreational health camp could promote positive changes in obese children lipid profile, thus contributing to healthy lifestyle promotion.

TAI CHI EXERCISE ALLEVIATES DEPRESSIVE SYMPTOMS AND INSOMNIA IN OLDER ADULTS

SIU, P.M., YU, A.P., YU, D.S., HUI, S.S., FONG, D.Y., WOO, J., CHUNG, K.F.
THE UNIVERSITY OF HONG KONG

INTRODUCTION:Depressive mood is often associated with sleep disorders. This study examined the effects of tai chi on improving sleep and mood in insomniac elderly with depressive symptoms.

METHODS: In this three-arm, single-blinded, randomised controlled trial, we recruited Chinese adults aged ≥ 60 years with chronic insomnia (diagnosed with Diagnostic and Statistical Manual of Mental Disorders, Fifth edition) and depressive symptoms (depression score of hospital anxiety and depression score or D-HADS ≥ 8) in Hong Kong community. Written informed consent was obtained before the study began. All experimental procedures received human ethics approval (HSEARS20120923002). Participants were randomly assigned to either control group (received no intervention), conventional exercise group (received 12-week generic exercise intervention three sessions weekly) or tai chi group (received 12-week tai chi intervention three sessions weekly). The primary endpoints were the remission of chronic insomnia and the change in D-HADS after 12-week post-randomization. Data were analysed by Chi-square test and generalized linear model using time and intervention as main effects with baseline as covariate. Pairwise comparison was conducted by closed test procedure. This study was registered on ClinicalTrials.gov (NCT02260843).
RESULTS: Between February 2014 and August 2016, 73 Chinese elders were randomly assigned to control (n=23), conventional exercise (n=24) or tai chi groups (n=26). After 12 weeks post-randomization, the remission rate of chronic insomnia of control, conventional exercise and tai chi groups were 0% (0 participants), 17% (4 participants) and 23% (6 participants), respectively. The remission rates of tai chi (P=0.014) and conventional exercise (P=0.041) groups were significantly higher than the control group. Main effect of intervention (P=0.035) was observed in D-HADS. Tai chi group (-32% in D-HADS) showed a significant larger alleviation in depressive symptoms compared with control group (-12% in D-HADS) (P=0.035). The D-HADS of conventional exercise group was reduced by 23%, however the improvement of conventional exercise group was not significantly greater than the control group.
CONCLUSION: These data demonstrated that a 12-week tai chi intervention alleviates insomnia and depressive mood in elderly with insomnia and depressive symptoms. Future study with a larger sample size is needed to determine the effectiveness of 12-week exercise intervention.

SKELETAL MUSCLE DYSFUNCTION IN AN ANIMAL MULTIPLE SCLEROSIS MODEL.

NIESTE, I., SPAAS, J., KEYTSMAN, C., VAN NOTEN, P., EIJNDE, B.O.

HASSELT UNIVERSITY

INTRODUCTION:In neurological disorders such as Multiple Sclerosis (MS), part of the neuromuscular dysfunction may reside within the affected skeletal muscle. We investigated hindlimb skeletal muscle properties in experimental autoimmune encephalomyelitis (EAE), an animal model for neuro-inflammation and demyelination that mimics MS.
METHODS: Skeletal muscle fiber cross-sectional area (CSA), fiber type proportion (m. tibialis anterior, TA) and ex vivo contractile properties (m. soleus, SOL & m. extensor digitorum longus, EDL) were investigated in EAE mice (18 and 28 days following EAE induction) and compared to healthy mice (n=60, 20/group).
RESULTS: EAE disease severity peaked at ~18 days and recovered slightly but not significantly at 28 days. Type IIa, IIx and IIb muscle fiber CSA was reduced in both the superficial/glycolytic and deep/oxidative part of the TA following 18 (-14 to 37%) and 28 days EAE (-18 to 33%). Following 28 days, there was an apparent shift towards a more glycolytic muscle (reduced type IIa, increased type IIb). Muscle CSA and maximal tetanic force of SOL and EDL were reduced following 18 (SOL: -11±20%, -21±19% and EDL: -11±30%, -22±21%, respectively) but not 28 days. Maximal tetanic force was inversely correlated with EAE disease severity (ρ SOL = -0.724 and ρ EDL =-0.632). For both SOL and EDL, muscle force/CSA was preserved (p>0.05). Submaximal force was unaffected compared to controls and the force-frequency relation had shifted leftwards at 18 days EAE but to a lesser extent at 28 days. Muscle fatigability during 10-minute repetitive stimulation was unaffected.
CONCLUSION: We observed significant structural and functional skeletal muscle alterations in EAE, identifying muscle tissue as a potential therapeutic target that may contribute to functional disability in EAE/MS. In EAE animals, hindlimb muscles underwent atrophy, shifted towards a more glycolytic phenotype and produced lower maximal force. Interestingly, the muscle seems to retain its plasticity, because some recovery was observed at 28 days (mainly in EDL), which may parallel the slight reduction in EAE disease severity. Therefore, future research is warranted to understand the underlying causes of skeletal muscle dysfunction in EAE and MS.

THE RELATIONSHIP OF OBESITY, SKELETAL MATURITY AND PHYSICAL FITNESS IN CHINESE PRESCHOOL CHILDREN

DANDAN, K.

HEALTH AND SPORTS SCIENCE & MEDICINE

Introduction: Globally, the prevalence of overweight and obesity among children is increasing [1]. Currently, a number of studies showed that childhood obesity negatively affects physical fitness performance. And some studies figured out that skeletal age is older than chronologic age in obese children [2]. However, there is limited evidence of obese children aged 3-6 years old. Therefore, purpose of this study was to explore whether childhood obesity affects skeletal maturity and physical fitness from earlier childhood.
Methods: In Shanghai, China, 325 children (195 boys: 5.2±0.8 years, 130 girls: 5.1±0.8 years) participated in this study. After the X-ray test of the hand and wrist, skeletal age was determined according to the Catalogue of National Standards of the People's Republic of China in 2005 (CHN05). Weight, height, and 6 physical fitness items were tested: standing long jump, 10m agility shuttle run, balance walking, sit and reach, tennis ball throwing and feet jump, following the standard of National Physique Examination for Chinese Children. BMI (kg/m2) was calculated by weight and height. Overweight and obesity were classified according to the age- and sex-specific BMI cut-off points developed by the International Obesity Task Force [3]. To compare the rate of physical fitness good performance and advanced skeletal age in different BMI groups, Chi-square Test was used. Significance was set at α= 0.05.
Results: The mean skeletal age was significantly greater than chronological age (mean 0.55 years, $p<0.01$) among all subjects. In 218 subjects (71.2%) the skeletal age was greater than the chronologic age. In 27 subjects (8.3%) the skeletal age was at least 2 years greater than the chronologic age. The rates of advanced skeletal age (more than one year) in different BMI-group were 27.3% (normal), 31.6% (overweight), 41.7% (obese) ($x2=4.073$, $p=0.131$). There was a significant positive correlation between advanced skeletal age and BMI ($r = 0.215$, $p<0.01$). The rates of physical fitness score over good performance line in different BMI-groups were 14.6%、 4.2% and 0.0%, respectively ($x2=15.529$, $p<0.01$). There is a significant negative correlation between physical fitness score and BMI ($r = -0.392$, $p<0.01$).
Conclusions : This study shows overweight and obesity significantly relates to the skeletal maturity and physical fitness performance in Chinese preschool children. It is suggested that it is necessary and important to prevent obesity from early childhood.

THE PRESENT STATUS OF SEDENTARY BEHAVIOR OF CHINESE TEENAGERS AND THE STRATEGY OF EXERCISE INTERVENTION

HE, Z., YANG, H.

PEKING UNIVERSITY

PURPOSE:
The sedentary behavior is the first independent risk factor for chronic non-communicable diseases and it has become the biggest public health problem in the 21st century. Based on the analysis of the status quo and harm of Chinese teenagers sedentary behavior, this paper explores the strategies of exercise intervention.
RESULTS:
1.Characteristics of the sedentary behavior.Recent national prevalence estimates from the 2016 Physical Activity and Fitness in China—The Youth Study (PAFCTYS) are presented. The survey revealed that 75.2% of young people reported at least 2 hours of sedentary behavior per weekday and 88.6% per weekend day (P < 0.01). Girls are more sedentary than boys on both weekdays (boys 74.9%, girls 75.5%) and on the weekend (boys 84.8%, girls 88.8%) (P < 0.01).At the same time, only about one-third (30%) of Chinese school-aged children met the recommended MVPA in 2016. Increasing screen-based time, particularly the use of the computer and internet and doing much homework are the main causes that contribute to the high levels of sedentary behavior.
2. Health hazards of sedentary behavior:(1)The "sedentary" lifestyle, the long use time of electronic products and the heavy tasks of classwork have led to the highest myopia rate among young people in China. The proportion of people with myopia was 45.7% for pupils , 74.4% for junior high school students , 83.3% for high school students and 87.7% for college students .(2) Long sedentary time and long-term bad sitting posture lead to the incidence of scoliosis among Chinese teenagers up to 20%. The overall ratio of male to female with scoliosis is about 1:3. (3) Doing Moderate-intensity exercise for 60-75 minutes per day reduces the risk of death from sedentary bahaviour. However, even if the recommended moderate-to-high intensity physical activity for 60 minutes per day is achieved, the sedentary behavior will still have an adverse effect on health when sitting still for a long time.
CONCLUSION: 1.Resistance exercises aimed at increasing muscle strength and improving the health condition of bone should be paid attention to in the stage of children and adolescents.
2.To reduce sedentary time, we encourage young people to take appropriate exercise during breaks, which can play the role of limiting screen time and alleviating visual fatigue.

EFFECTIVENESS OF HIGH-INTENSITY INTERVAL TRAINING ON FAT LOSS AND HEALTH BENEFITS IN OVERWEIGHT AND OBESE ADOLESCENT: A META-ANALYSIS

ZHU, L.1, LIU, J.X.2

1.GUANGZHOU SPORT UNIVERSITY, 2.SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION:The purpose of this study was to quantitatively evaluate the effect of high-intensity interval training (HIIT) on fat loss and health benefits in overweight and obese adolescents through meta-analysis, and to promote the application of HIIT in overweight and obese adolescents.
METHODS: The relevant literature was searched from the databases of PubMed, Web of Science, Embase, the Cochrane library, and CNKI. Two researchers were independently selected the literature, evaluated the quality and extracted data according to the exclusion criteria. All the data extracted were conducted quantitative synthesis using the software of Revman 5.3 and Stata12. 0.
RESULTS: A total of 11 RCTs with 488 overweight and obese adolescents were included. Compared with control group, HIIT significantly decreased body weight (MD=-1.73 kg, 95%CI: -3.25~-0.21, p=0.02), BMI (MD=-1.42 kg/m2, 95% CI: -1.97~-0.87, p<0.0001), body fat percentage (MD=-1.70%, 95%CI: -2.94~-0.45, p=0.0002), waist circumference (MD: -1.80 cm, 95%CI: -3.5~-0.10, p=0.04); decreased fasting blood glucose (MD=-0.07 mmol/L, 95%CI: -0.18~-0.04, p=0.02), fasting insulin (MD=-0.66, 95%CI: -0.84~-0.47, p<0.0001), insulin resistance (MD=-0.66, 95%CI: -0.84~-0.47, p<0.0001), and improved peak oxygen consumption (SMD=0.99, 95%CI: 0.47~1.51, p<0.00001). Sensitivity analysis revealed that HIIT reduced total cholesterol (MD=-0.32 mmol/L, 95% CI: -0.49~-0.15, p=0.0002), low-density lipoprotein (MD=-0.42 mmol/L, 95% CI: -0.56~-0.28, p<0.0001) and triglyceride (MD=-0.19 mmol/L, 95% CI: -0.29~-0.08, p=0.0003) were superior to the control group.
CONCLUSION: HIIT can effectively improve body composition, glycemic control, lipid metabolism, and cardiorespiratory fitness in overweight and obsess adolescent.

PHYSICAL ACTIVITY AND EXERCISE BEHAVIOURS SIX MONTHS PRIOR TO AND DURING PREGNANCY

HOPKINSON, Y.1, FELLOWS, L.2, HILL, M.D.3, FRYER, S.1

1: UNIVERSITY OF GLOUCESTERSHIRE , 2: UNIVERSITY OF WORCESTER, , 3: SWANSEA UNIVERSITY .

INTRODUCTION:There is a growing body of evidence to suggest that regular physical activity (PA) and exercise prior to and during pregnancy has positive health benefits for both mother and baby. These benefits include, but are not limited to: reducing rates of gestational diabetes, pre-eclampsia, lower back pain and increased self-esteem and overall wellbeing. However, there is little data describing the current PA and exercise behaviours before and during pregnancy. As such, the current study aimed to determine PA and exercise behaviours six months pre and during pregnancy.
METHODS: 308 participants completed an electronic survey to explore their PA and exercise behaviours 6-months prior, and during pregnancy. Participants were recruited using social media groups using convenience and snowballing sampling. All participants were asked to report the time spent sitting, as well as the average number of days per week that they engaged in PA and/or exercise for at least 30 minutes per day in the six months prior to pregnancy and during their pregnancy, as well as the type of PA or exercise. Data were analysed using SPSS with α set at 0.05. Data is presented as mean difference (MD) and 95% confidence intervals (CI).
RESULTS: The amount of PA was significantly reduced during pregnancy compared to six months prior (P<0.0001, MD=0.85, 95% CI=0.66-1.03, d=0.518). In addition, the number of days of exercise was also significantly lower during pregnancy compared to six months prior (P<0.0001, MD=0.98, 95% CI =0.82-1.15, d=0.668). One hundred and forty-two participants reduced their PA participation since becoming pregnant, with 9 reporting that they no longer did any PA, and 168 participants reduced their exercise participation since

becoming pregnant, with 62 reporting they no longer did any exercise. 55.19% of participants indicated that the type of PA they engaged in had changed since becoming pregnant. Walking, running, attending the gym and exercise classes were the most popular activities prior to pregnancy but all were reduced in popularity during pregnancy, whereas participation in yoga and swimming increased during pregnancy. Over half of the participants (53.9%) reported that they have decreased the duration of their PA since becoming pregnant, and 62.01% reported decreasing the intensity of their PA. When asked if they spent more time sitting now they are pregnant, 60.39% of participants responded yes. When the group was split according to trimester, this increased to 73.4% of participants who were spending more time sitting in the third trimester.
CONCLUSION: The main finding of this study is that the volume, duration and intensity of PA and exercise is reduced during pregnancy, whilst sedentary time is increased. Given the physical and mental health benefits of PA and exercise to both mother and baby, future research should seek to understand 1) why this behaviour change occurs, and 2) what preventative strategies could be viable in counteracting this.

BONE PROPERTIES IN MALE COLLEGE ATHLETES - COMPARISON OF KENDO AND OTHER SPORTS -

HONDA, A., KAMURO, R., TSUCHIDA, H., INOUE, M., ADACHI, S., SUGAJIMA, Y.

ASAHI UNIVERSITY

INTRODUCTION:High-impact sports, such as volleyball and basketball, have remarkable positive effect on bone mass and strength, on the other hand non- or low-impact sports, such as swimming and cycling, have less effect on bones. In kendo, irregular and large amount of impacts are directly exerted on the right leg (fumi-komi-ashi; the foot which stamps on the floor with the entire sole). However, there are only few studies focused on bone parameters in kendo players. Here, the aim of this study was to investigate relationship between sports characteristics, body compositions, physical fitness and bone parameters in male young athletes.
METHODS: Subjects were male college athletes and non-regularly exercised students. They were divided into 3 groups based on sports characteristics (impact for heel), Kendo; kendo (n=29, 18.6±0.5 yr), Low; non-regular exercised, cycling and ski (n=23, 18.7±0.5 yr) and High; volleyball and handball (n=24, 18.6±0.5 yr). Bone parameters at calcaneus were measured by ultrasound using A-1000EXP Ⅱ. Measurement side was right in kendo players and the dominant leg (greater impact was loaded) side in others. Body composition were measured by BIA using Inbody 470. The 50m-dash, standing broad jump and vertical jump were measured as power parameters.
RESULTS: The bone stiffness (BS) of High were significantly higher than the other 2 groups (respectively $p<0.01$). However, there were no significantly difference among Kendo and Low. The broadband ultrasound attenuation (BUA) of High was significantly higher than Low ($p<0.05$). The speed of sound (SOS) of High was significantly higher than other groups ($p<0.01$ in Kendo and $p<0.05$ in Low). The vertical jump of Kendo was significantly lower compared to other groups (respectively $p<0.01$). There were no significantly correlations between body weight, lean body weight, body mass index, powers and BS.
CONCLUSION: The benefit of high-impact sports on bone parameters were shown, as previous studies. However, contrary our expectation, we could not find benefits of Kendo on bones. Cyclists perform weight training several times per week. Non-regularly exercised students had sports experience, such as soccer and baseball, during their high school days. Thus, in Low group, many mechanical stress are/were loaded on bones, as well as Kendo. Therefore, greater effects of Kendo on bones compared to Low might not be shown, in this study. On the other hand, we also could not find any relationships among body composition, powers and BF. These factors are very important for bone health. More detail analysis including nutrition will be needed in further studies.

DIFFERENT PROTOCOLS OF PHYSICAL TRAINING ON THE MARKERS OF METABOLIC SYNDROME AND ITS RELATIONSHIP WITH BUTYRYLCHOLINESTERASE ACTIVITY IN ADOLESCENTS

NEIVA, C.M., VILELA-TERRA, G.D.S., SILVA, G.R., PESSOA-FILHO, D.M., VERARDI, C.E.L., MAFFEI, W.S., CIOLAC, E.G., PEREIRA, C.B., BORGES, L.A.A., MELLO, L.S., GUIMARÃES, B.

UNESP

INTRODUCTION:Metabolic syndrome (MS) represents an important public health problem worldwide and has been attracting the attention of researchers around the world, due to your virtuous growth. By presenting a multifactoral etiology, its rapid diagnosis is essential, as well as the correlation with biomarkers that signal early the presence of lipid imbalances that lead to the development of the disease, such as butirilcolinesterase (BChE). The objective of the study was to investigate the possible association between the activity of BChE, indicators of MS and the practice of three different methods of training: aerobic, strength and concurrent training, in adolescents carrying the MS.
METHODS: Were selected to carry out training protocols, 80 teenagers aged 16 to 19 years, obese and presenting changes to the following MS indicators: waist circumference, total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides, blood glucose and blood pressure. The participants were divided into four homogeneous groups (n = 20): aerobic training group (AT), strength training group (ST), concurrent training group (CT) and an untrained control group (UT), where held four training sessions during the week, each session lasting 60 minutes, making a total of 12 weeks of practice, except the UT, who were untrained during the period of the study.
RESULTS: At the end of the training period it was possible to note that all training methods were effective in improving the majority of the indicators analyzed, However, in comparing the types of training the aerobic training was demonstrated to be the most efficient for the improvement of the most analyzed indicators and the only one that interfered in the values of the BChE, comparing them to those of eutrophic individuals.
CONCLUSION: In this way, we can conclude that physical exercise programs demonstrate to be an efficient and low cost non-pharmacological method of therapeutic intervention for the treatment and control of MS.

INTERACTIONAL INFLUENCE OF EXERCISE HABITS AND RISK FACTORS OF METABOLIC SYNDROME ON MEDICAL EXPENSES IN JAPANESE ADULT MEN

OKADA, K., OHKAWARA, K., KATSUKAWA, H.

THE UNIVERSITY OF ELECTRO-COMMUNICATIONS

INTRODUCTION:The morbidity and mortality rates of metabolic syndrome and lifestyle diseases in exercisers have been reported to be low, namely that people who exercise regularly are less prone to metabolic syndrome and related lifestyle diseases. Currently, it is estimated that Japanese medical care expenditure has surpassed 42 trillion yen in 2016, which puts intense pressure on national finances. Almost one-third of this medical burden is owing to lifestyle diseases. Some models suggest that increased exercise will reduce the

number of medical patients, specifically, people at risk from lifestyle diseases, and suppress total medical expenses. However, in Japan, research on the relationship between exercise habits and medical expenses is limited.
The aim of this study is to clarify the relationship between medical costs, exercise habits, and metabolic syndrome using data from consecutive medical check-ups and medical prescriptions between 2012 and 2014.
METHODS: We analyzed the data of 2,999 males (43.1±9.6yrs) living in Japan, with records of medical expenses, exercise habits, and a diagnosis of metabolic syndrome from at least three consecutive annual medical check-ups. The study excluded 5% of these data with excessively high medical expenses in order to prevent bias. Also, the study did not focus on women because of the small number of female patients with metabolic syndrome. The definition of exercise habits was inferred from the questionnaires regarding regular check-ups.
We extracted information on blood pressure, serum lipid, fasting blood glucose, HbA1c, abdominal girth, and BMI as risk factors of metabolic syndrome from the medical check-up data. The relative costs of diabetes, hypertension, and dyslipidemia were calculated using patient prescriptions. Judgment of illness (existing patients, those at high risk for developing metabolic syndrome, and non-patients) was inferred from patient prescriptions.
The study used an analysis of variance (ANOVA) to elucidate how various factors of both medical expenses and blood data were interrelated.
RESULTS: Our analysis of this three-year period indicated that the interaction between exercise habits, time and judgement of metabolic syndrome does not have a significant impact on medical bills, but each main effects have significant impacts on them.
Results indicated that people who exercise regularly have significantly lower medical expenses than those who do not, as well as fewer risk factors for developing metabolic syndrome.
CONCLUSION: Overall, these results suggest that medical expenses are suppressed for non-patients with metabolic syndrome than for patients and those with a high risk of developing it. Also, these data suggest that people who exercise regularly are at a lower risk of developing metabolic syndrome. However, exercise habits may not offset conditions for developing metabolic syndrome in medical expenses in Japanese adult men.

INFLUENCE OF A MOUTH RINSE INTERVENTION ON COGNITIVE FUNCTION IN A DEMENTIA PREVENTION PROGRAM

SHIRAI, A.1,2, WADAZUMI, T.1, KURODA, K.1, HAMADA, N.1, HIRATA, Y.1, YOSHIMOTO, T.1

1: KANSAI UNIVERSITY, 2: OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION:When mouth rinsing with a carbohydrate solution (mouth rinse), oral receptors within the mouth sense carbohydrates and directly stimulate the reward centers in the brain, which improve its working capacity and performance. In addition, physical exercise is an effective strategy for improving the cognition of elderly people with mild cognitive impairment (MCI), related to the activation of the dorsolateral prefrontal cortex of the brain. Therefore, this study aimed to examine the influence of a mouth rinse on cognitive function in a preventive care program.
METHODS: Eleven participants (aged 72.45 ± 5.18 years, three males and eight females) were recruited from a Japanese preventive care community program for the elderly. The participants completed 11 sessions of the program within three months, which consisted of a cognitive task (80 min) and a dual task block exercise (30 min). Throughout the program, a 6% glucose solution was taken as a mouth rinse every 15 min. The control group consisted of 33 participants (aged 73.57 ± 4.58 years, nine males and 24 females) who participated in the same task-based program without the mouth rinse intervention. To measure cognitive function, a Trail Making Test (TMT) was used in the first session before the intervention and in the last session after the intervention. TMT scores (sum of Part A and Part B) were analyzed using paired t-tests and independent t-tests. Comparisons were made between pre- and post-intervention, as well as between the intervention and control groups.
RESULTS: In the intervention mouth rinse group (n = 11), the average TMT time significantly decreased from 205.36 sec (pre-intervention) to 194.54 sec (post-intervention) ($p < 0.05$). The decrease in the average TMT time was greater in the intervention group as compared with the control group. The p-value was close to being statistically significant (n = 33) ($p = 0.05$).
CONCLUSION: As a result of the mouth rinse intervention in the cognitive deterioration prevention program that spanned three months (11 sessions), participants TMT scores significantly improved. The results imply that the intervention group maintained cognitive function better than the control group. Even in the control group, there were participants with improved cognitive function without mouth rinsing; however, mouth rinsing may add more value to the maintenance of cognitive function in the elderly. Moreover, the results cannot distinguish between the effects of integrating a mouth rinse into an exercise program as compared with a cognition program. Participants in this study were also unable to control their diet or exercise; thus, we need to consider the influence of other factors in future experiments. This study revealed that a carbohydrate mouth rinse may enhance the effects of exercise and cognition programs to prevent dementia.

A PRACTICAL STUDY OF NOGUCHI TAISO IN CREATIVE LESSON AT A VOCATIONAL SCHOOL IN JAPAN : EFFECTIVENESS OF ITS REPETITIVE EXPERIENCES DURING TWO YEARS

HATANO, Y., OTAKE, R.

KOBE SHINWA WOMEN'S UNIVERSITY

INTRODUCTION:"Noguchi Taiso", a method of teaching exercise established by Michizo Noguchi (professor emeritus of Tokyo University of the Arts, 1914-1998), has unique characteristics that emphasizes an importance of muscle relaxation rather than muscle strengthening. The authors have been studying on effectiveness of this method in a regular dance class for students of a university or a vocational school (Hatano & Otake, ECSS 2016, AEISEP 2018). In these previous studies, the authors obtained some positive results by analyzing free-description responses from students at a single experience of Noguchi Taiso, but there was a limitation because of a small number of participants. Here the authors report results of our improved approach with a large scale.
METHODS: Questionnaire survey was conducted once in a year during consecutive two years for 159 students of a vocational school to clarify how effectively Noguchi Taisho worked as a teaching tool for a dance class. Noguchi Taiso lesson was given by a specialist (one of its successors). Open-ended questions were asked to describe physical and emotional changes before and after receiving the lesson. A text mining method was used for analysis of collected data (KHcoder).
RESULTS: Text mining found no difference in quantitative and qualitative features of computer-sorted words between current and previous surveys. However, further analysis by creating a co-occurrence network with these words revealed that a word, "water", was more close-

ly linked to "flowing" in the second-year survey than in the first-year survey. In addition, a linkage between positive-minded expressions such as "concentration" and "consciousness" appeared more frequently in the second-year survey and a linkage between negative-minded words such as "weak" and "bad" declined. These results suggested importance of repetitive Noguchi Taiso exercises to effectively draw out its prominent characteristics known as relaxation.
CONCLUSION: Conclusions
The Noguchi Taiso method can be more optimally operated in school lessons by repetitive experiences than one-time experience.

EFFECT OF AN ADAPTED PHYSICAL ACTIVITY (APA) PROGRAM ON QUALITY OF LIFE, FEAR OF FALLING AND PHYSICAL PERFORMANCE OF WOMEN WITH OSTEOPOROTIC VERTEBRAL FRACTURES: EFFECT SIZE FOCUS.

MARINI, S.1, MASINI, A.1, SANNA, T.1, RAGGI, A.1, BUFFA, A.2, MALAVOLTA, N.2, MAIETTA LATESSA, P.1, LEONI, E.1, DALLOLIO, L.1

ALMA MATER STUDIORUM UNIVERSITY OF BOLOGNA

INTRODUCTION:Bone fractures are the main consequences of osteoporosis as representing a serious obstacle to aging in good health and compromising independence, quality of life and lifespan. Patients with a vertebral fracture should be considered for anti-fracture therapy including physical activity (Kendler, 2016). The aim of this study was to measure the efficacy of our APA protocol in terms of quality of life, fear of falling and physical fitness and, in particular, to evaluate if the adherence had an effect on these outcomes.
METHODS: The APA group performed 1 hour twice a week for 6 months exercise protocol, specific for osteoporosis, while the Control Group (CG) received the generic indication on the importance of physical activity. The outcomes assessed at the baseline and at the end of the study were: quality of life (ECOS-16), fear of falling (FES-1), functional exercise capacity (6MWT), balance and gait (Tinetti Scale), flexibility of the column (Chair Sit & Reach). Effect sizes (EF) were calculated using Cohen's d. To assess the potential impact of adherence, we divided the APA group according to the adherence percentage: 75% versus >75%, to evaluate if there is an effect on the main outcomes.
RESULTS: All patients who completed the study and participated in more than 50% of lessons were included in the analyses (40 women): 22 of the APA group and 18 of the CG. The adherence calculated as number of sessions performed compared to the sessions proposed was 75.8% (from 56.4% to 97.8%). According to Cohens' d, a "big" effect (>0.8) of the intervention was observed for 6 outcomes (ECOS-16, ES: 1.204; FES-I, ES: 1.007; 6MWT, ES: 1.390; Tinetti Scale, ES: 0.871; Balance, ES: 0.969; Chair Sit & Reach Left, ES: 1.000) and a "medium" effect (>0.5) for 4 outcomes (VAS, ES: 0.510; Borg Scale, ES: 0.654; Gait, ES: 0.639; Chair Sit & Reach Right, ES: 0.739). The number of sessions attended by APA group did not have a significant impact on the results, but slightly influenced the effect size of some items such as: Tinetti Scale (ES: 0.903), Gait (ES: 0.889) and Balance (ES: 0.863).
CONCLUSION: The big effect sizes suggest that our APA protocol have clinical significance in addition to being statistically significant. There is no significant dependence demonstrated by Cohens d between improvement in tests and adherence. Therefore, the improvement can be also achieved in those who do not reach the cut-off of 75%, but who nevertheless attended at least 50%.

RELATIONSHIP BETWEEN PRESCHOOL CHILDRENS PHYSICAL ACTIVITY LEVEL, THEIR FAMILYS EXERCISE HABIT AND AWARENESS

ISHIZAWA, J.1, SASAKI, R.2

1: SHIRAYURI UNIVERSITY , 2: KEIO UNIVERSITY

INTRODUCTION:Promoting physical activity (PA) among preschool children is very important. PA is considered to be affected by home lifestyle and awareness of parents (Hinkley et al.2008). Thus, this study examines the relationship between the physical activity level of preschool children and the exercise habit and awareness of their families.
METHODS: Participants were 83 preschool children (37 boys, 46 girls) aged 3–6 years and their parents. Childrens PA was measured using a triaxial accelerometer (Active Style Pro, Omron) for five consecutive days during the time spent in nursery school (9 a.m. to 4 p.m.). Their PA was examined by measuring step count and time spent in moderate to vigorous physical activity (MVPA). Parents filled a 4-point Likert scale questionnaire on their own and family's preference and frequency of exercise. Based on the parents answers, this study divided the children into two groups (high and low frequency or like and dislike exercise) and compared both groups PA.
RESULTS: In the case of boys, no significant differences of childrens step count and MVPA due to parents' exercise preferences were observed. However, comparing the time spent on children's MVPA in girls, the parents' "like exercise" group showed a significantly higher level of PA than the "dislike exercise" group. On the other hand, there were no significant differences between childrens PA due to parents and families' frequency of exercise for both boys and girls.
CONCLUSION: Therefore, this study suggests that the PA of preschool children may be affected by the parents preference of exercise when it comes to girls. Previous studies showed that children with active parents tend to be more active (Moore et al.,1991; Sallis JF et al.,1998), and that preschool boys are more active than preschool girls (Pate et al., 2004; Cauwenberghe et al.,2012). To increase girls' physical activity, it may be necessary to consider their families' awareness of exercise.

THE EFFECT OF PHYSICAL ACTIVITY ON THE PHYSICAL AND MENTAL HEALTH CONDITIONS OF CHILDREN WHO EXPERIENCED STRESSFUL LIFE EVENT

SAKAMOTO, Y.1, OKAZAKI, K.1, UEKI, S.2, SUZUKI, K.3

1: TOHOKU GAKUIN UNIVERSITY, 2: OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES, 3: JUNTENDO UNIVERSITY

INTRODUCTION:After the Great East Japan Earthquake, in the affected area a decrease in the physical activity of children has been reported due to various factors (1). On the other hand, from the previous studies on the physical and mental health of children after the disaster, long-term effects on their health condition such as chronic stress are pointed out (2). Therefore, in this study, we examined the influence of the amount of physical activity of children after 6 months of the disaster on the change of physical and mental health afterwards.
METHODS: We conducted a thorough investigation of all 199 children from the 4th to 6th grades of elementary school living in the afflicted municipality in eastern Japan coastal area. This longitudinal study included five inventory surveys in September 2011 (6 months after the disaster), March 2012 (1 year later), March 2013 (2 years later), March 2014 (3 years later), March 2015 (4 years later). The subjects gathered at the gymnasium between 15:00 and 16:00 on the day of the survey, and after explaining the survey method, stimulated whole saliva samples were collected using Sali-kids Salivette tube, and saliva flow (SF; ml/min), secretory IgA (SIgA) concentration (SIgA-C; μg/ml), SIgA secretion rate (SIgA-SR; μg/min), and cortisol concentration (COR; μg/dL) were determined. We investigated the amount of physical activity (total exercise time per week (PAwk), sitting position time (weekday, holiday)) and childrens health related QOL (PedsQL Japanese version) by self-written questionnaire. Statistical analysis was carried out using a general linear model (SPSS ver. 24).
RESULTS: Significant period variation was observed in all saliva measurements of SF, SIgA-C, SIgA-SR and COR ($p<.05$). Next, the subjects were divided into two groups at the median of PAwk, sitting position time and PedsQL score at 6 months after the disaster, and the effect on variation of each saliva index was examined. As a result, it was observed that PAwk, holiday sitting time and PedsQL after 6 months affected COR fluctuation ($p<.05$).
CONCLUSION: It was suggested that the physical activity level and the state of QOL have long-term effects on physical and mental health in children after experiencing stress full life events.

STUDY OF THE COGNI-CISE ON THE PHYSICAL-INTELLIGENT FITNESS IN SENIORS

CHE-CHUN, K., TA-CHUN, C., HSIU-HUA, W., CHUN-JU, L., CHIU-TIEN, H.

NATIONAL CHUNG CHENG UNIVERSITY

INTRODUCTION:With the increase of age, the degradation of physical function could cause muscle loss, disability, fall and chronic diseases in aging seniors. Psychological cognitive dysfunction has been indicated as one of the common mental health problems in elderly people. Regular exercise can effectively improve the physical fitness, lower prevalence of chronic diseases and the mortality in elderly people (1). While the blood flow of individuals brain was increased during exercise, the oxygen uptake in the brain was also increased. Therefore, the cognitive function could be maintained and the degradation of brain function could also be postponed (2). In addition, Japanese scholars have suggested that cognitive function could be improved by walking with cognitive activity (3). Therefore, this study developed a set of Cognitive Exercise (Cogni-cise) with cognitive activity and functional training to improve the ability to perform daily activities and cognitive function in elderly people.The purpose of the study was to determine the effects of Cogni-cise on functional fitness and cognitive function in elderly people.
METHODS: Elders over 65 years of age from the Douliu City Family Education Center in Taiwan were recruited to participate in this study. Sixteen (73.5 ± 5.95 years old) eligible subjects attended two 90-minute multicomponent exercises training courses in one week for three months. The functional fitness and the Mini-Mental State Examination (MMSE) were measured before and after the training program. The data was analyzed by SPSS 21.0 for Windows. Descriptive statistics, and dependent sample t-test were used. The significant level was set to $\alpha=.05$.
RESULTS: After the 12-week Cogni-cise program, the functional fitness of the elderly was significantly improved($p<0.05$): lower body flexibility (9.05±10.96 cm > 1.58±12.12 cm,$p=.003$), grip strength (28.36±7.9 kg > 126.16±6.11 kg,$p=.013$), upper body muscle strength (20.38±5.46 reps > 14.63±2.52 reps,$p=.001$), lower body muscle strength (21±3.48 reps > 13.31±2.89 reps,$p=.000$), closed eye soft surface (1.51±0.52 SI < 2.25±0.86 SI,$p=.003$), agility/dynamic balance (5.8±0.65 sec < 6.88±0.89 sec,$p=.000$), cardio respiratory fitness (112.06±13.94 reps > 97.81±13.07 reps,$p=.001$). Furthermore, the language understanding, space concept and operational ability in cognitive function were also improved significantly ($p=.002$). However, there was a non-significant increasing trend in the overall score of cognitive function.
CONCLUSION: The intervention of 12-week Cogni-cise program could have profound improvements in physical function and cognitive function for the elderly. Therefore, the Cogni-cise may have benefits for improving ability to perform daily activities in the elderly and alleviating the impact of aging.

EFFECTS OF A 12-WEEK WALKING FOOTBALL INTERVENTION ON HEALTH AND FITNESS OUTCOMES IN MEN AND WOMEN; STUDY PROTOCOL

MCBAIN, T., BARKE, D., BROOM, D.R.

SHEFFIELD HALLAM UNIVERSITY

Background: The health benefits of association football are evident with participation improving cardiovascular and musculoskeletal fitness [1]. However, the physicality of the sport is difficult to sustain with advancing age due to reduced functional capacity, more prone to injury and increased recovery time. Walking football is a small-sided alternative, predominantly played men aged ≥55 years. Whilst mobility is likely to have decreased, participants use technical attributes and skill to win, thus competition and enjoyment are retained. Despite the popularity of walking football, there is a paucity of studies examining the health and fitness benefits of walking football [2,3].
Methods: Following ethical approval, using a repeated-measures design, 11 participants (n = 9 males, n = 2 females; mean age ± standard deviation [SD], 60 ± 1 years) were recruited by Sheffields Drink Wise, Age Well community health scheme to a 12-week walking football program. The program consisted of one 60-minute session per week predominantly playing competitive games post warm up. Outcomes measured were body mass index (BMI), waist circumference, resting blood pressure, non-fasting blood lipids, physical activity levels and six-minute walk distance. These were assessed at baseline (week-0), midpoint (week-7) and post-intervention (week-13). Sessional RPE was recorded after each session. After checking the distribution of data, repeated-measures ANOVA and the Friedman's test were used to analyse intervention differences (week 0-13). Effect sizes were calculated using partial eta squared (0.01 small, 0.09 medium, ≥0.25 large) and Kendall's w (0.2 small, 0.5 medium, ≥0.8 large).
Results: Adherence to the 12-week intervention was 55%. Mean (± SD) attendance for sessions was 64% (range; 0-92%). Mean rating of perceived exertion was 6 (range; 3-9). Analysis revealed significantly reduced BMI ($p<0.05$, $w=0.51$), total cholesterol ($p<0.05$, $w=0.78$), diastolic blood pressure ($p<0.05$, $\eta p2=0.49$) and time spent sedentary ($p<0.05$, $w=0.64$). Despite favorable changes with small-to-large effect sizes, non-significant differences were observed with all other outcome measures. No differences were shown between week-0 and week-7 measures.
Conclusion: The study suggests the potential efficacy of walking football as a public health intervention for older populations, however, meaningful changes only occur beyond 7 weeks. Future research should explore if there is a dose response relationship and the efficacy of other walking modified interventions (e.g. Netball).

THE MEDIATING EFFECT OF STRESS ON THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND SLEEP QUALITY AT THE END OF A SEMESTER IN COLLEGE STUDENTS

ZHANG, Z., HE, Z., CHEN, W.

UNIVERSITY OF MICHIGAN; PEKING UNIVERSITY

INTRODUCTION:College students report experiencing poorer sleep quality at the end of a semester due to the increased levels of academic stress. Physical activity (PA) has been identified as a key factor in improving sleep quality in college students. However, the relationship between PA and sleep quality at the end of a semester and the mechanism underlying this relationship have remained unexplored. This study aimed at examining the association between the PA and sleep quality at the end of a semester in college students, and determining if the stress level mediated this association.
METHODS: 398 college students (223 males and 175 females, mean age = 19.04 years) voluntarily completed a set of questionnaires measuring PA, sleep quality, and stress in the week before final exams in 2017. PA was assessed using the International Physical Activity Questionnaires. The metabolic equivalent (MET)-minutes per week were calculated to indicate the levels of PA. Sleep quality was measured using the Pittsburgh Sleep Quality Index, and stress was measured using the Perceived Stress Scale. According to a widely used procedure to test mediation, three multiple regression models were performed. First, stress (mediator) was regressed on PA (independent variable). Second, sleep quality (dependent variable) was regressed on PA (independent variable). Finally, sleep quality (dependent variables) was regressed on both PA (independent variable) and perceived health (mediator). Age, gender were controlled as covariates in all models. The normality of data was confirmed by checking the skewness and kurtosis of each variable.
RESULTS: The first model showed that PA was a significant predictor of stress ($\beta = -0.24$, $p < 0.001$), indicating that higher levels of PA were associated with lower levels of stress at the end of a semester. In the second model, PA significantly contributed to the sleep quality ($\beta = 0.13$, $p = 0.009$) suggesting that higher levels of PA were linked with better sleep quality. In the third model, stress was a significant predictor of sleep quality ($\beta = 0.55$, $p < 0.001$). However, after controlling for the stress in the third model, the regression coefficient of PA was no longer significant ($\beta = 0.003$, $p = 0.92$), indicating that PA was not correlated with sleep quality when stress was controlled for. Overall, the results from the three models suggested a fully mediating effect of the perceived stress level on the relationship between PA and sleep quality at the end of a semester in college students.
CONCLUSION: Higher levels of PA are associated with better sleep quality in the week before final exams among college students. Moreover, this positive association is fully mediated by the perceived stress level.

RELATION BETWEEN BODY COMPOSITION AND DIETARY SUPPLEMENTS CONSUMPTION IN FITNESS CENTERS PRACTITIONERS

SCHLICKMANN, D.S.1, CASTRO, E.A.2,3, MOLZ, P.1,4, SANTOS, C.1, SILVA, T.G.1, SOARES, G.M.1, MULLER, C.1, LAMPERT, L.1, PEREIRA, W.A.S.1, PRÁ, D.1, FRANKE, S.I.R.1

1 UNIVERSITY OF SANTA CRUZ DO SUL ; 2: UNIVERSITY OF FRANCA ; 3: LFE RESEARCH GROUP, UNIVERSIDAD POLITÉCNICA DE MADRID ; 4: PONTIFICAL CATHOLIC UNIVERSITY OF RIO GRANDE DO SUL

INTRODUCTION:Fitness centers have generated enormous market potential for the dietary supplements industry. These products have been a great ally among fitness centers practitioners who seek changes in body composition, aiming mainly the muscle mass gain. The objective of this study was to compare the body composition between fitness center practitioner consumers and non-consumers of dietary supplements.

METHODS: This study was approved by the Research Ethics Committee of the Universidade de Santa Cruz do Sul - Brazil. Four hundred and seventy-nine individuals attending fitness centers of both sexes, aged between 18 and 78 years, were divided into two groups: consumers and non-consumers of dietary supplements. Body composition was assessed by bioimpedance (OMRON®). Height was measured and body mass index (BMI) was calculated as body weight/height (kg/m2). Supplement consumption was determined using an online questionnaire developed for this study. Test T and Mann Whitney were used for mean comparison according to the distribution of data. Chi-square was employed for frequency comparison. Analyses were performed in men and women separately. The significance level adopted was p≤.05.
RESULTS: Men consumed more supplement more than women (45.3% vs 27.2%, p<.001). In men, consumers group was younger compared to non-consumers group (31.7±10.7 years vs 35.8±13.0 years, p=.026), although no significant difference was observed for body composition variables in men (p>.05). In women no difference was observed in age between consumers and non-consumers groups (37.5±14.3 years vs 38.6±13.5 years, p=.436). With the exception of height, in women, all body composition variables analyzed showed significant differences between consumers and non-consumers groups, respectively: weight (61.1±9.4kg vs 66.2±11.1kg; p<.001), BMI (23.2±6.6kg/m² vs 24.9±3.7kg/m²; p<.001), muscular mass (29.4±4.7% vs 27.1±3.7%; p<.001), visceral fat (4.9±2.1% vs 6.1±2.5%, p<.001) and total body fat (30.8±7.8% vs 35.3±7.1%; p<.001). From total of women that consumed dietary supplements, 54.8% were oriented by nutritionists or physicians, while only 27.8% from total of consumers men sought specialization orientation (p=.001).
CONCLUSION: The consumption of dietary supplements did not alter body composition in men, while consumers women presented a more favorable profile of body composition that their non-consumers counterparts. Adequate guidance seems to be the key factor to obtain effective results in the use of dietary supplementation, which may contribute to the improvement of body composition and health parameters.

THE ADHERENCE TO AND EFFECTS OF EXERCISE TRAINING IN BREAST CANCER PATIENTS ON TAMOXIFEN.

FALKMANN, M.A.M., VRIELING, A., WEMPE, J.B.

UNIVERSITY OF GRONINGEN, UNIVERSITY MEDICAL CENTER GRONINGEN

INTRODUCTION:Exercise training (ET) has a positive effect on acute and chronic side effects of anti-cancer therapy. It has been shown that it has a high efficacy in preventing cancer-related fatigue and improving quality of life. Also, ET-programs during and after cancer treatment may result in some positive effects on physical factors (1, 2). A common adjuvant treatment in breast cancer patient is hormonal therapy such as tamoxifen. The use of tamoxifen reduces the risk of the cancer returning by blocking oestrogen receptors in cancer cells, however it is also associated with several side effects (3). Tamoxifen may influence respiratory responses on exercise which may limit the effects of exercise training. In this pilot study, we investigated the adherence of breast cancer patients using tamoxifen to an exercise training program; in addition, the effects on cardiovascular parameters were studied.
METHODS: A total of 50 female patients, mean age 56 year, were enrolled in the study. Inclusion criteria were a diagnosis of breast cancer, for which they had been treated, adjuvant treatment with tamoxifen, and capability of performing a rehab program, with exercise training as main part. The program of 12 weeks consisted of 2-3 weekly supervised group ET-sessions, in addition to psychosocial or dietary support. The amount of the weekly ET-sessions depends of the classified group, which correlated with the personal goal of the patient. They performed a cardiopulmonary exercise test (CPET) before and after the program, measuring work load, oxygen consumption, and anaerobic threshold (AT). Paired-sample t-tests on difference scores were used to compare pre- and post-CPET parameters.
RESULTS: All participants were able to perform the exercise program, however thirteen did not perform a post-CPET and were excluded from the study. Data are presented on the remaining 37 participants and no distinction were made according to the classified ET-group. Participants showed an improvement of peak oxygen consumption of 8% (SD=11,4). Maximal work load, AT and oxygen pulse increased by 12%(SD=9), 19%(SD=33) and 7%(SD=13) respectively. There were no significant differences found for the HRmax, RER or ventilatory efficiency.
CONCLUSION: Our study shows a positive effect of exercise training in patients with breast cancer, who are on adjuvant therapy with tamoxifen. It suggests that breathing abnormalities induced by the hormonal treatment may have a limited role in exercise training. The next step is to find out whether the response in this group is substantially different from similar patients, but without adjuvant therapy.

EFFECTS OF AEROBIC DANCE EXERCISES COMBINING RESISTANCE ELEMENTS ON PHYSICAL FITNESS CHARACTERISTICS OF THE ELDERLY PEOPLE

NISHIZAWA, T.

SIGAKKAN JUNIOR UNIVERSITY

INTRODUCTION:The purpose of this study is to investigate the influence of Aerobic Dance Exercise (ADEx) combining resistance elements on physical fitness characteristics of the elderly people. The muscular strength associated with aging will decrease. It is important to understand the influence of aging on muscle strength of lower limb. Resistance training has been shown to be the most effective exercise for improving muscle strength. Therefore, in order to prevent the muscle weakness of elderly people, we prescribed Resistance, Aerobic Dance Exercise (R-ADEx), centering on steps with a high load on the lower limbs.
METHODS: 23 healthy elderly people(13 women and 10 men) aged 63.66 ± 6.66 volunteered for this study. Elderly people performed R-ADEx for 2 months period once a week in health course. We measured morphology, muscular strength, physical strength two months before and at the end of exercise.
Exercise content: The content of the program was R - ADEx and resistance circuit training. R-ADEx exercise duration is about 30 minutes. R-ADEx incorporates many steps (squat, lunge, hamstring curl, knee lift, jump etc.) with high load on the lower limbs. Music pitch is set to BPM of 115 to 120. At the circuit training, the participants made 3 laps of 5 items (abdominal curl, push-up, side raise, arm curl, rat pull-down.
Physical Fitness Test: Items were ability to balance (the method using single-leg standing with eyes open.), walking for 6 minutes (endurance), walking with obstacles and grip strength.
Morphology measurement: We measured the lower limb skeletal muscle mass using the body composition meter InBody 430 (BioSpace) and measured the thigh circumference with major. Muscle strength: Knee joint extension isometric leg strength was measured with T.K.K. 5710 m (Takei Co., Ltd.).

RESULTS: As a result, knee joint extension isometric leg strength did not change. There was no change in skeletal muscle mass of the leg and circumference of the thigh. In the physical fitness test, the balance ability, walking for 6 minutes, walking with disability showed a significantly high value.
Results of physical fitness tests showed that men had a greater rate of increase than females.
CONCLUSION: In the present study, after 2 months of Aerobic Dance Exercise combining resistance elements on the lower limbs, no improvement in muscle strength was observed. There was no change in the skeletal muscle mass and the circumference of the thigh circumference, which are factors of muscle strength. There was no muscle hypertrophy due to exercise. On the other hand, walking ability and balance ability were effective. It was suggested that R - ADEX was effective in improving the neuromodulation mechanism.Men were more effective than women when doing the same exercise. It is a future task to prepare a program that will be effective for female as well.

THE EFFECTS OF AEROBIC AND RESISTANCE EXERCISE ON BODY MASS IN OBESE WOMEN WITH DIFFERENT GENOTYPES

ANDRIEIEVA, O., DROZDOVSKA, S., SAVENKO, V., VINNICHUK, Y.U., POLISHCHUK, A.
NATIONAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORT OF UKRAINE

INTRODUCTION:Genetic factors are estimated to contribute from 30% to 70% to the development of obesity (1). The intensity of metabolism and excessive body weight by is determined 77% by heredity, and only 23% depend on environmental factors including lifestyle [2]. The genetic factors associated with the development of obesity include a number of single nucleotide polymorphisms of the PPARA, PPARG, LEPR genes. The objective of the work was to determine the effects of aerobic and resistance exercise on body weight in obese women with different genotypes.
METHODS: the body weight, BMI, body composition and body circumferences of 39 obese women involved into Zumba fitness and 30 obese women involved into resistance training were evaluated before and after the 3-month exercise period. DNA was isolated from buccal epithelial cells. RNA was extracted from monocytes. G/C (PPARA) (rs4253778), Pro/Ala (PPARG), Q233R (LEPR) gene polymorphisms and gene expression were studied using real-time quantitative PCR. The body composition was determined with TANITA device.
RESULTS: The body weight and body fat percentage measures did not differ significantly among the carriers of the PPARA G/G and G/C genotypes. In the group of women with the G/C genotype, the level of visceral fat was by 6% and waist circumference was by 12% higher than in the women with the G/G genotype. The exercise training induced the changes in the activity of the gene. Expression of the PPARA gene in both groups was changed by 83% ($P < 0.05$).
In women with the Pro/Ala+Ala/Ala genotype, the 3-month aerobic training caused significant changes in body weight, body composition, and a slight decrease in body circumferences. For women with the Pro/Pro genotype, a more substantial weight loss was observed along with a significant reduction in the circumference of the waist and hips.
The women carriers of the Q allele and the Q/Q genotype had the higher levels of leptin than carriers of the R/R genotype. The proportion of women with the above-normal leptin levels among the carriers of the R/R genotype was by 39% lower than among the carriers of the Q/Q genotype. The R-allele and the R/R-genotype of the LEPR gene contribute to decrease in leptin level after resistance training. The most significant changes induced by resistance exercise were observed in women with the R/R-genotype of the LEPR gene.
CONCLUSION:
The most significant effect of aerobic training on body weight was observed in woman carriers of the Ala-allele of the Pro/Ala polymorphism of the PPARG gene. The largest changes in body composition after the resistance training program were found in women carrying R-alleles of the LEPR gene.

EFFECT OF A STRENGTH TRAINING PROGRAM ON IGF-1 IN OLDER ADULTS WITH OBESITY AND HYPERTENSION: PILOT STUDY

TREJO, M., GALAVIZ, R., BORBÓN, J., ALARCÓN, E., PINEDA, H., FERNÁNDEZ, R., ARRAYALES, E., TAPIA, E.
UNIVERSIDAD AUTÓNOMA DE BAJA CALIFORNIA

INTRODUCTION:The insulin-like growth factor I (IGF-1) is an important metabolic biomarker associated with a variety of health and exercise related outcomes (1). Aging is associated with decreased activity of GH and the GH / IGF-1 axis, resulting in a reduced concentration of IGF-1 and a reduction in the function of the signaling pathway of IGF-1 (2) In addition, there is a progressive decline in muscle mass and function (sarcopenia) (3). IGF-1, produced in skeletal muscle during exercise is also released into the circulation and could contribute to an increase in circulating levels of IGF-1 (4). The aim of the study was, without a doubt, a strength training program on IGF-1 in older adults with obesity and hypertension.
METHODS: 8 older adults (58.7 ± 1.9 years old) with obesity and hypertension were evaluated for maximum upper and lower train strength (1RM). Subsequently they performed 2 weeks of anatomical adaptation to 70% of the 1RM and 4 weeks of strength training to 70% of the 1RM, the frequency was 4 alternating days per week, of which, 2 days of upper train work (vertical traction, horizontal and vertical thrust) and 2 days of the lower train (knee and hip extensors, plantar flexion). IGF-1 was determined in blood and analyzed by ELISA method.
RESULTS: The mean initial and final concentrations of IGF-1 were 79.2 ± 22.2 ng/dl and 83.7 ± 23.8ng/dl, respectively, showing a significant increase after the implementation of strength training ($p < 0.05$).
CONCLUSION: The training of the strength of 2 semans of anatomical adaptation (40% of 1RM), 4 weeks (70% of 1RM) and frequency 4 in older adults with obesity and hypertension, produces increases in IGF-1, this could be an effective proposal to combat the effects of aging on muscle mass.

RELATIONSHIP BETWEEN LEVEL OF PHYSICAL ACTIVITY AND QUALITY OF SLEEP IN WOMEN

MURAOKA, Y., KAMEDA, R.

MEISEI UNIVERSITY

INTRODUCTION:It has been reported that people with daily exercise and activity do not experience sleeping difficulties or hardship during daytime awakening. Many previous studies have targeted men; however, few have studied the relationship between physical activity and sleep in view of the female menstrual cycle. Therefore, this study aimed to clarify the relationship between physical activity and sleep quality while considering the specific menstrual cycle phases.
METHODS: Participants were 10 female college students. For 61 days, from September 01-October 31, 2018, basal body temperature was measured daily to identify the menstrual cycle phase. Fitness wristband (Fitbit, charge 2) measured the amount of physical activity and quality of sleep. We analyzed each stage of the menstrual cycle and examined the relationship between the amount of physical activity and quality of sleep.
RESULTS: There was no statistically significant difference in the amount of physical activity in each stage of the menstrual cycle in all items. Along with body temperature, activity level also increased during the luteal phase and the number of steps and distance traveled decreased during the menstrual period until the follicular phase.
No significant difference was found between the stages of the menstrual cycle regarding sleeping time and quality of sleep. Physical activity was divided into two groups of low activity and high activity, and sleep quality was compared between both groups. In the low activity group, during the menstrual period, the rate of deep sleep and REM sleep was decreased (from 39% to 26%) and rate of arousal was increased (from 11% to 14%). On the other hand, in the high activity group, no significant change was observed even during the menstrual period, and the quality of sleep was not deteriorated.
CONCLUSION: In the luteal phase where body temperature rises, the amount of physical activity increases; however, women with less daily activity may not be able to ensure quality of nighttime sleep corresponding to it, as compared to women with more daily physical activity. On the other hand, it is suggested that women with a large amount of daily physical activity may experience improved sleep quality during the luteal phase without lowering sleep quality during the menstrual period.

EFFECTS OF WHOLE-BODY ELECTROSTIMULATION VERSUS CONVENTIONAL RESISTANCE TRAINING ON CARDIOMETABOLIC HEALTH IN SEVERLY OBESE INDIVIDUALS: PRELIMINARY RESULTS OF A RANDOMIZED-CONTROLLED TRIAL

RELJIC, D.1,2, HERRMANN, H.J.1,2, GERL, A.1,2, WEIDLICH, K.1,2, NEURATH, M.F.2, ZOPF, Y.1,2

UNIVERSITY HOSPITAL ERLANGEN

INTRODUCTION:Obesity, particularly in conjunction with further cardiometabolic risk factors (e.g. hypertension, hyperglycaemia, hyperlipidemia), is associated with an increased risk for cardiovascular disease and mortality. Physical activity (PA) programs and dietary modifications are cornerstones of therapeutic interventions to treat obesity-related risk factors. In addition to aerobic exercise, resistance training (RET) is an important component of PA-interventions targeted at improving cardiometabolic health. Whole body electromyostimulation (WB-EMS) is an innovative, time-efficient type of RET that can provide positive effects on body composition and muscle strength. However, while the positive impact of conventional RET on cardiometabolic health is well established, the effects of WB-EMS on respective risk markers in severely obese individuals have yet to be determined.
Here, we present preliminary data from a randomized-controlled study comparing the effects of WB-EMS (20 min/session) and RET (60 min/session), each in combination with nutritional counselling (NC), on cardiometabolic health in obese individuals.Here, we present preliminary data from a randomized-controlled study comparing the effects of WB-EMS (20 min/session) and RET (60 min/session), each in combination with nutritional counselling (NC, aim: –500 kcal deficit/day) on cardiometabolic health in obese individuals.
METHODS: Thirty-five obese subjects (55±12 yrs, BMI: 37.9±8.2, 45.8±6.4 %body fat) with at least 2 additional cardiometabolic risk factors were randomized to either 12 weeks of WB-EMS (n=12), RET (n=10) or a control group only receiving NC (CON, n=13). Body mass (BM), %body fat (%BF), maximum strength (Fmax) of major muscle groups (abdominals, upper/lower back, chest and legs), selected cardiometabolic risk indices and Metabolic Syndrome Z-Score (MetS) were determined baseline and after 12 weeks.
RESULTS: WB-EMS and RET were both well tolerated and no adverse events occurred. BM and %BF were significantly reduced in all groups (WB-EMS: –4.1 kg, –1.4 %; RET: –3.9 kg, –1.4 %; CON: –3.1 kg, –1.0 %). WB-EMS and RET significantly improved Fmax in all examined muscle groups. Total cholesterol-, LDL-and HbA1c-concentrations decreased in the WB-EMS group (all $P<0.001$). RET reduced waist circumference ($P<0.001$) and mean arterial blood pressure ($P<0.05$) and improved overall cardiometabolic risk (MetS, $P<0.001$). In CON, Fmax-values did not improve and none of the cardiometabolic risk markers were not altered after 12 weeks.
CONCLUSION: The preliminary results of this study indicate that WB-EMS can be considered as a feasible and time-efficient option to RET for improving body composition, muscle strength and various cardiometabolic risk markers in severely obese individuals. Moreover, these findings underpin the crucial role of exercise in improving health outcomes, that goes far above simple weight loss. The final data of this still ongoing study will allow more definitive conclusions.

EFFECT OF THE MODERATE AEROBIC TRAINING ON REPRODUCTIVE FUNCTION OF FEMALE RATS EXPOSED TO A HIGH-FAT DIET

GONÇALVES, B.S.M., KUBOTA, M.C., PONSONE, G., CARDOSO, G.N., SILVA, A.R.F., SARNO, T.A., RIBEIRO, A.L., STADELLA, D., LE SUEUR-MALUF, L.

FEDERAL UNIVERSITY OF SAO PAULO - UNIFESP

INTRODUCTION:High dietary fat intake, with or without the development of obesity, has been provenly associated with impaired reproductive function. In this context, moderate physical exercise applied as a non-pharmacological tool may provide beneficial effects on female reproductive functionality and fertility. Thus, the present study aimed to investigate the effect of the moderate aerobic physical training on reproductive parameters in female rats exposed to a hyperlipidic palatable diet.
METHODS: Female Wistar rats (12 weeks old) were distributed into 4 groups (Ethics Committee CEUA 8816291116) during 4 weeks: a) High-fat diet + Not training (HNT group; rats fed a high-fat diet (Nuvilab®, milk chocolate, peanut, cornmeal cracker, in the ratio of 3: 2: 2: 1, respectively) and not trained; b) High-fat diet + Training (HT group; rats fed a high-fat diet and submitted to exercise training); c) Standard diet + Not training (SNT group; rats fed a Nuvilab® standard diet and not trained); d) Standard diet + Training (ST group; rats fed a standard diet and submitted to exercise training). The exercise sessions were performed in a treadmill 5 times a week during the 4 weeks of the study. The intensity of exercise was adjusted weekly (30 minutes at 50% of VO2max; 40 minutes at 50% of VO2max; 40 minutes at

60% of VO2max; 50 minutes at 60% of VO2max reached in a maximum running test). Body mass gain, ovarian mass and periovarian adipose tissue weigh were measured. In addition, growing ovarian follicles and corpora lutea were quantified by histological methods. The comparison among the groups was performed using General Linear Model (GLM; software IBM SPSS Statistics 20), considering the following independent factors: diet (high-fat or standard) and aerobic training (trained or not trained). Results are mean + SD and $p<0.05$ was considered statistically significant.
RESULTS: High-fat diet increased significantly ($p=0.0001$) body mass gain (HNT=36.90+/-15.29; HT=36.05 +/-18.07; SNT= 15.40 +/-9.50; ST= 18.55+/-8.26 g) and periovarian adipose tissue (HNT=2.54+/-1.01; HT= 2.85+/-1.64; SNT=1.79+/-0.67; ST= 1.76+/-0.91 g). No effect of exercise was observed. Ovarian mass was affected neither by exercise training nor by high-fat diet. Exercise training decreased significantly ($p=0.026$) the number of primordial/primary follicles (HNT=6.80+/-7.08; HT=4.20+/-3.15; SNT= 9.22+/-4.49; ST=3.80+/-4.36). No effect was observed for preantral, antral, or mature follicle numbers and also for the number of corporea lueta and atretic follicles.
CONCLUSION: Our results indicated that exposition to high-fat diet for 4 weeks had no effect on morphological ovarian parameters. Unexpectedly, exercise decreased the number of primordial/primary follicles without affecting other ovarian morphological parameters. Additional studies are needed to evaluate the effect of exercise on ovarian function and oocyte quality in rats exposed to high-fat diet.

PERCEPTION OF THE FEMALE ATHLETE TRIAD IN FEMALE LONG-DISTANCE RUNNERS

KIDO, E., UEDA, T., OZAKI, Y.
HIROSHIMA UNIVERSITY

INTRODUCTION:Low energy availability, amenorrhea, and osteoporosis have been reported as health problems in female athletes and is called the "Female Athlete Triad (FAT)". FAT is crucial in female athletes who undergo continuous exercise training and is attributable to the shortage of available energy, which is the state wherein energy consumption exceeds energy intake. It also causes amenorrhea and osteoporosis. Menstruation is an important mental and physical health index for females, and irregular menstruation and amenorrhea due to FAT can hinder the possibility of future pregnancy and cause osteoporosis. Irregular menstruation is also speculated to be associated with fatigue fractures and performance deterioration. Thus, normal menstruation could be one of the indices to protect the health of female athletes. The athlete herself, however, might lack knowledge about their menstruation. Therefore, the purpose of this study was to examine the present situation regarding the concept of menstruation in female long-distance athletes. We eventually intend to develop an educational system and environment wherein female athletes can maintain their health while competing.
METHODS: The subjects of this survey were 36 female long-distance runners comprising 17 high school runners and 19 university runners. The subjects participated in a questionnaire survey.
RESULTS: Altogether, ten athletes (29%) reported currently having menstrual cycle abnormalities, 14 (40%) had menstrual cycle abnormalities in the past, and 11 (31%) reported having normal menstruation.
CONCLUSION: Regarding their perception of menstruation, more than 30% of the subjects indicated that "It is annoying having menstruation". Thus, we found that there is a tendency to feel annoyed with regular menstruation. Nearly half of the subjects (45%) answered positively in relation to " rare menstruation and amenorrhea caused by intensive training and dietary restrictions are unavoidable". Moreover, 80% of the subjects answered positively for the item "Top athlete tends to have many menstrual abnormal athletes". Therefore, it seemed that an incorrect perception of menstruation had been established. Moreover, 41% of the subjects agreed to the item " Good menstruation cycle is dispensable if the competitive ability improves", which indicated that female runners tend to deprecate the value of regular menstruation, and in turn good health, for the sake of improvement in their competitive ability. Furthermore, regarding the coach's knowledge of the menstrual cycle of an athlete, 8% of the respondents indicated that they were disgusted to discuss their menstrual with male coaches. In conclusion, under these circumstances, it is necessary for coaches to manage their athlete's menstruation and provide support. Using the knowledge generated in this study, we intend to develop an effective educational program that educates female athletes regarding the importance of regular menstruation, and thus, help them maintain their health while also competing.

History

NEW ELEMENTS ON THE UNEVEN BARS IN WOMEN'S' ARTISTIC GYMNASTICS

NAKASONE, M., KODO, D.
TOKYO GAUGEI UNIVERSITY

Introduction
More than 250 Uneven ber elements have recently been recorded in the Fédération Internationale de Gymnastique Code of Points. However, there are few theses on the history of when such elements were introduced. The purpose of this study is to create such a history for the Uneven bar (UB) in women's artistic gymnastics and to suggest new elements that may appear in the future.
Methods
he method of study was undertaken by bibliographic analysis. This article refers mainly to journals that were published by the Japan Gymnastic Association, and a list that was made regarding the occurrence of new elements on the UB in women's artistic gymnastics.
Results and discussion
From the analysis, the author gatherd data regarding various elememts that were performed. For example, "Swing forward to double salto backward tucked" was performed by Shaposchnikova N. A in the 1977 world cup games. "Swing down between bars - swing forward to double salto backward tucked with 1/1 turn (360°) in first salto" was performed by Morio. M in the 1982 Japan national Championships. Another example, "Giant circle backward to handstand with hop 1/1 turn (360°) in handstand phase" was performed by Chusovitina. O in 1991 pre-Olympic games. "Swing backward with 1/2 turn (180°) and straddle flight backward over HB to catch HB" was performed by Khorkina.S in the 1992, "Swing forward to double salto backward stretched with 2/1 turn (720°)" was performed by Yamawaki. K in 1999 Japan national Championships. In recent years, "Swing farward to double salto backward tucked with 3/2 turn (540)" was performed by Mustafina. A in the 2010 Would Championships. "Facing outward on LB - Clear pike circle backward through handstand with flight to hang on HB" was performed by Komova. V in the 2011 Would Championships. The development of new elements has been greatly influenced by the improvement of the apparatus itself and by the change of rules over the years. In the future, we can expect that new elements will be created by adding twists to existing elements.

Molecular Biology and Biochemistry

IRON METABOLISM RELATED PARAMETERS AND REFERENCE VALUES FOR EVALUATING IRON STATUS IN CHINESE ATHLETES

ZHENG, J., ZHANG, Q., WU, X., SUN, M.
SHANGHAI RESEARCH INSTITUTE OF SPORTS SCIENCE

INTRODUCTION:Iron nutrition status is closely related with athletes health and exercise performance. However, traditional evaluation system for iron status based on biochemical markers of serum ferritin (SF) and hemoglobin (Hb) may easily lead to miscalculation of iron deficiency. The purpose of this study was to investigate Chinese professional athletes' iron status by comprehensive iron metabolism related markers and to establish reference values for this population. The focus of this study was the introduction of soluble transferrin receptor (sTfR) and TfR-F index (sTfR/Log SF) into the evaluation system of athlete's iron status.
METHODS: Hematological and biochemical markers of 227 healthy athletes (84 men and 143 women) from Shanghai professional sports teams were analyzed in order to establish reference values of SF, sTfR, TfR-F index and hepcidin that is specific for Chinese athletes. Correlation analysis was also taken to investigate the relationships of iron status with sex hormone (testosterone) and oxidative stress (SOD, MDA).
RESULTS: Among the parameters related to iron metabolism, SF, TfR-F index and hepcidin were significantly different between male and female athletes while sTfR showed no significant difference between genders. The reference values of SF were proposed as 30ng/mL for male athletes and 12ng/mL for female athletes. The threshold of sTfR was determined as 25nmol/L. TfR-F index combined SF and sTfR, and the thresholds were set as 15 for male athletes and 22 for female athletes. The reference value range of hepcidin was 4-54ng/mL for male athletes and 1.5-43ng/mL for female athletes. SF showed a positive correlation with oxidative stress in apparently healthy athletes and testosterone was negatively correlated with hepcidin and TfR-F index.
CONCLUSION: The iron evaluation system we established here included sTfR, TfR-F index and hepcidin in addition to conventional iron parameters. The expanded system and proposed reference values could provide more comprehensive information about athletes iron status. This is important for sports physicians and nutritionists to make more justified intervention decisions and reduce the risk of unnecessary iron supplementation.

BONE METABOLISM MARKER (U-NTX) IN TOP-LEVEL FEMALE VOLLEYBALL ATHLETES

WAKAMATSU, K., SAKURABA, K., FUJITA, S., SANOMURA, M., GUSHIKEN, T., OGAWA, Y., IWASAKI, M.
J.F.OBERLIN UNIVERSITY

INTRODUCTION:Female athletes are often forced to leave competitions for a long time owing to female athlete triad of health disorders, which include amenorrhea (menstrual disorder), osteoporosis, and eating disorders (1). Overuse injuries, such as stress fractures, are serious problems faced by athletes. In general, female athletes with low bone density, which indicate bone intensity and amenorrhea, are presumed to have a high risk of developing overuse osteopathy including stress fractures. However, it is difficult to predict the incidence of stress fractures by bone density alone, because athletes with low bone density do not always develop stress fractures, but still perform well in competition. While various markers of bone density exist, results do not always reflect the bone conditions at the time. In contrast, a bone metabolism marker that can evaluate generalized bone metabolism behavior through blood and urine concentration, can reflect the precise state of blood at that certain time. These markers have drawn recent attention for their potential utility as stress fracture prevention markers (2). The purpose of this study was to examine the usability of some bone metabolism markers to prevent overuse injury of bones in young female volleyball players.
METHODS: In this study, we recruited 20 female senior high school volleyball athletes (SVA) and 17 female university volleyball athletes (UVA). We measured the bone metabolism marker of type 1 collagen crosslinked N-telopeptide in urine (u-NTX) in both groups.
RESULTS: U-NTX levels in the SVA and UVA groups were and 90.2 ± 38.9 and, 67.7 ± 23.9 nmol bone collagen equivalents/mmol creatinine, respectively, which showed a significantly higher level in the SVA than UVA group ($p < 0.05$).
CONCLUSION: We conducted a questionnaire survey and measured bone metabolism marker by urine samples in top-level female senior high school and university volleyball athletes. Bone metabolism marker (u-NTX) levels were significantly higher in senior high school athletes than university volleyball athletes ($p < 0.05$). The results presented above suggest that u-NTX is higher in female aged 15-18 years than over age 20 years and may reflect continued skeletal maturation.

EFFECT OF A SINGLE BOUT OF NEUROMUSCULAR ELECTRICAL STIMULATION ON SECRETED PROTEIN ACIDIC AND RICH IN CYSTEINE

MIYAMOTO, T., SHIMIZU, Y., MATSUO, Y., OKAMOTO, H., KANZAWA, Y., OTARU, T., MIYAMAE, N., TAKEDA, C., FUJIOKA, H.
HYOGO UNIVERSITY OF HEALTH SCIENCES

INTRODUCTION:Epidemiological studies have shown that physical activity and exercise can prevent the onset of colon cancer. However, the mechanisms by which physical activity and exercise may induce the beneficial effect on colon cancer remain unclear. Secreted protein acidic and rich in cysteine (SPARC), which is a secreted skeletal muscle protein, is known as one of the potential mediators responsible for suppressing colon tumorigenesis (Tai T, et al., 2008). Serum SPARC has been reported to response to 30 min aerobic exercise at high intensity (Aoi W, et al., 2013). However, there are many people who cannot perform such a high-intensity physical exercise because of orthopedic problems or frailty. Our previous studies have shown that neuromuscular electrical stimulation (NMES) had a potential to be

an alternative exercise method (Miyamoto T, et al., 2018). Additionally, although we found that NMES successfully induced serum brain derived neurotrophic factor, which is one of myokines (Miyamoto T, et al., 2018), the response of serum SPARC levels to NMES has been unknown. Therefore, the purpose of this study is examining the response of blood SPARC levels to NMES in healthy adults.
METHODS: Nineteen healthy adult men (20.9 ± 0.8 years old) randomly performed two experimental sessions; a 30-min NMES to both legs and a session of complete rest for 30 min (CON). Heart rate was monitored throughout each session, and blood examinations for serum SPARC, glucose and lactate levels were performed before and after each session. All variables were analyzed using two-way repeated measures analysis of variance with session and time as within-participant factors.
RESULTS: The maximum heart rate during NMES session was 125.5 ± 17.4 bpm. There was a significant interaction between session and time for SPARC levels ($p < 0.05$), and NMES significantly increased SPARC levels compared to CON ($p < 0.05$). In addition, NMES induced higher lactate concentration and lower glucose levels than CON (both $p < 0.05$).
CONCLUSION: Our main finding is that NMES could increase serum SPARC levels. It has been reported that SPARC interacts with 5' adenosine monophosphate-activated protein kinase (AMPK) (Song H, et al., 2010) and that glycogen-depleting exercise is associated with an increase in free AMPK (Philp A, et al., 2012). Our present result that NMES significantly lowered glucose levels might had increased serum SPARC levels through the increase of AMPK in healthy young adults. Therefore, there is a possibility that NMES can be one of exercise methods for preventing colorectal cancer. It is necessary to investigate intervention research using NMES in middle-aged and elderly people in the future.

EFFECT OF URIC ACID ON EXERCISE-INDUCED OXIDATIVE STRESS IN HUMAN

KAMBAYASHI, I.1, KIMOTO, R.2, TSUKAMOTO, M.3, TOGO, M.4, AKIZUKI, A.5, UCHIDA, E.6

1: HOKKAIDO UNIVERSITY OF EDUCATION, 2: FUJI WOMEN'S UNIVERSITY, 3: TOKAI UNIVERSITY, 4: RITSUMEIKAN UNIVERSITY, 5: HEALTH SCIENCES UNIVERSITY OF HOKKAIDO, 6: TAISHO UNIVERSITY

INTRODUCTION:Uric acid (UA), the final product of purine metabolism, is known as a powerful antioxidant in humans (1). A previous study demonstrated that temporary administration of UA (500 mg) raised the concentration of UA in blood, which increased serum antioxidant capacity and reduced exercise-induced oxidative stress (EIOS) in a healthy population (2). In addition, it is likely that the increase of UA in blood after exercise is a protective response to EIOS (3, 4). Therefore, we studied the effect of UA on EIOS in humans based on a hypothesis that UA acts as an antioxidant to prevent from EIOS.
METHODS: Prior to participating in this study, all subjects provided both verbal and written consent. Forty-one male students (age 20.1±1.6 yr, height 175.3±5.0 cm, weight 68.7±7.3 kg) belonging to the physical education course in the University performed incremental exhaustive cycle exercise (IE, n=11), high-intensity intermittent sprint cycle exercise consisting of a 7-s sprint at maximal effort and a 53-s recovery for 20 times (HI, n=18) and moderate aerobic cycle exercise at the identical intensity of 50%VO2peak (MA) for 30 min, 60 min and 90 min (n=12), respectively. Peripheral blood was collected before exercise (Pre), immediately after exercise (Post) and 1.5-hour after exercise (Recovery) for analyzing UA concentration. Urine samples were also collected at Pre and Recovery for analyzing urinary 8-hydroxydeoxyguanosine (8-OHdG) level as the oxidative stress maker.
RESULTS: Both UA concentration and 8-OHdG level significantly increased at Recovery in IE and HI. However, no change was found in MA30, MA60 and MA90, respectively. There was the significant positive correlation ($r=0.687$, $p<0.01$) between UA concentration and 8-OHdG level for the pooled Recovery data from all five exercise despite no relationship for the pooled Pre data. The significant positive correlation ($r=0.712$, $p<0.01$) was also found in amount of change from Pre to Recovery of UA concentration and 8-OHdG level.
CONCLUSION: We did not obtain the evidence that UA prevents from EIOS. This result suggests that UA is not a main factor against EIOS.

LACTOBACILLUS PLANTARUM TWK10 SUPPLEMENTATION CHANGES THE ENERGY HARVESTING FROM VERY-LONG CHAIN FATTY ACID TO IMPROVE EXERCISE PERFORMANCE

CHEN, W.

CHANG GUNG UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION:Lactobacillus plantarum TWK10 (LP10) is a probiotic known to improve endurance exercise performance. Here we analyze the proteomics and metagenomic changes in a LP10 supplemented mouse model.
METHODS: Male ICR mice were divided into 2 groups to receive by oral gavage either vehicle or 1.03x109 CFU/kg/day of LP10 for 6 weeks. Liver tissue damage markers were determined. Quantitative LC-MS/MS-based proteomic profiling of livers from mice supplemented with LP10 was performed to provide baseline knowledge of the LP10 treated proteome. Additionally, proteins changes by LP10 treatment were subjected to the Ingenuity Pathway Analysis (IPA) to provide corroborative evidence for differential regulation of molecular and cellular functions affecting metabolic processes. Fecal samples were obtained from each mouse and the microbial community profile analyzed by pyrosequencing of the 16S rRNA genes using a Roche 454 pyrosequencer.
RESULTS: Serum ALT and LDH levels were significantly lower in the LP10 treated group. Of the 880 identified proteins, 25 proteins were significantly downregulated and 44 proteins were significantly upregulated in the LP10 treated compared to vehicle group. In metagenomic data, LP10 supplementation induced a shift in the gut microbiota composition towards butyrate-producing members such as the taxa Firmicutes and Clostridium.
CONCLUSION: This suggests that energy may be provided from lipid oxidation since peroxisomal fatty acid oxidation in liver is employed to provide energy source to other organs such as muscle to enhance endurance exercise performance. Additionally, changes in the regulation of proteins through LP10-supplementation may affect other vital biological processes related to energy harvesting in liver.

ASSOCIATION BETWEEN PLASMA IL-10 AND PHYSICAL ACTIVITY LEVELS

TAULER, P., RODAS, L.L., RIERA-SAMPOL, A., AGUILO, A., MARTÍNEZ, S.

UNIVERSITY OF THE BALEARIC ISLANDS

INTRODUCTION:Exercise has anti-inflammatory effects, and therefore, regular physical activity can protect against the development of chronic metabolic and cardiorespiratory diseases, as well as against conditions such as insulin resistance or atherosclerosis. This effect

may be mediated via a reduction in body fat mass, specifically in visceral fat mass. The aim of this study was to determine the association between physical activity levels and plasma concentrations of both pro-inflammatory and anti-inflammatory cytokines.
METHODS: A descriptive cross-sectional study with 240 participants (112 men and 128 women, age 30.8±10.5, BMI 23.0±3.4 kg/m2) was conducted. Participants in the study were between 18 and 55 years old, healthy, non-smokers, and engaged in as much as 10 hours of weekly physical activity. Fasted blood samples were taken for the measurement of plasma IL-6, IL-10, TNF-alfa and IL1-beta concentrations. Physical activity levels were determined using the short version of the IPAQ questionnaire. IPAQ score was calculated as MET-hour/week. Bioimpedance was used to determine anthropometrical parameters. Data was analysed to determine the presence of significant associations.
RESULTS: Mean participants' IPAQ score was 43.8±36.1 MET-hour/week and sitting time on a week day was 6.7±2.9 hours. Plasma IL-10 levels were positive and significantly associated with the IPAQ score (r=0.232, p=0.040). However, no association was found between IL-10 and the scores for each exercise intensity category considered (walking, moderate and vigorous). On the other hand, IL-10 levels showed a significant but inverse association with the sitting time (r=-0.191, p=0.036). When the contribution of participants' age, gender and anthropometrical characteristics on these associations were analysed, no significant contributions were found, with body fat percentage being a possible mediator (p=0.071). No significant associations were found between IL-6, TNF-alfa or IL1-beta plasma levels and physical activity parameters considered.
CONCLUSION: Physical activity levels are associated with concentrations of the anti-inflammatory cytokine IL-10. This association reflects the anti-inflammatory effect of physical activity. This effect is likely to be induced by low body fat percentage. However, the study design does not allow to determine a cause-effect relationship. It is noteworthy that this association was found in spite of the present study was performed in a, on average, young population, and that subjects with high physical activity levels (more than 10 hours per weeks) were not included in the study.

THE EFFECTS OF EXERCISE VOLUME, INTENSITY, AND MODALITY ON INFLAMMATION, MTDNA COPY NUMBER, TELOMERASE ACTIVITY, AND TELOMERE LENGTH

SHIN, Y.A.1, KIM, C.S.2, CHANG, E.W.3, LEE, S.H.3, PARK, D.H.3
1DANKOOK UNIVERSITY, 2DONGDUK WOMENS UNIVERSITY, 3INHA UNIVERSITY

INTRODUCTION:Previous researches on telomeres have demonstrated that shortened telomere length (TL) is a hallmark characteristic of aging (1) and is associated with a number of chronic diseases such as cardiovascular disease, cancer, dementia, and mortality (2). The well-established health benefit of physical activity (PA) has been demonstrated to preserve LTL, but has yet to draw clear conclusions about the volume of PA or exercise. For instance, Ludlow et al. (3) suggested that the very low or high level of PA have an inverse relationship (U curve) with the LTL. Furthermore, the study of the difference in LTL according to the modality and intensity of exercise is very rare. Therefore, the purpose of this study was to investigate the effects of exercise volume, intensity and modality on inflammation, mtDNA copy number, telomerase activity, and the telomere length (TL).
METHODS: The study participants consist of male elite cyclists (n = 40), bodybuilders (n = 40) aged 40 to 50, and their age-matched active adult control group (n = 40). Relative TL was determined from peripheral blood leukocytes by quantitative real-time polymerase chain reaction. Volume, intensity and modality of exercise were self-reported.
RESULTS: There was no difference in the exercise energy expenditure per week between the control group and the cyclist group, but exercise intensity was significantly higher in the cyclists (p<.01) and the bodybuilders (p<.001) than the control. The concentration of lactate dehydrogenase (LDH) in control showed a higher than in athlete groups (p<.001). Telomerase activity and TL in control showed a lower than in athlete groups (p<.01). TL was a positive associated with mtDNA (p<.01) and telomerase (p<.01), but a negative associated with LDH level (p<.01). mtDNA showed a positive association with telomerase (p<.01) but an inverse association with LDH (p<.05).
CONCLUSION: These results suggest that regardless of exercise modality, regular moderate to high intensity exercise may protect TL by reducing inflammation and increasing levels of telomerase activity and mtDNA copy number in middle-aged men.

EFFECTS OF CHRONIC EXERCISE COMBINED WITH DIETARY RESTRICTION ON THE ULTRASTRUCTURE AND METABOLISM OF SOLEUS MUSCLE IN WBN/KOB-FATTY RATS

SHIROYA, Y.1, YAMAUCHI, H.1, KUROSAKA, Y.2, MINATO, K.3, TAKEMORI, S.1
1: THE JIKEI UNIVERSITY SCHOOL OF MEDICINE , 2: JUNTENDO UNIVERSITY , 3: WAYO WOMENS UNIVERSITY

INTRODUCTION:WBN/Kob-Fatty (WKF) rats lack Leptin receptor and develop chronic pancreatitis and diabetes with obesity. Our recent analysis of ultrastructure and metabolism of their pancreatic tissue indicated that adequate habitual exercise combined with dietary restriction could improve pancreatic exocrine and endocrine dysfunction preventing the development of diabetes. The aim of this study was to investigate the effects of chronic exercise combined with dietary restriction on the ultrastructure and metabolism of soleus muscle and its relation to the improvement of their diabetes associated with obesity.
METHODS: Male WKF rats (age, 6 weeks) were divided into Fatty-Obese (FOB; n=10), Fatty-Diet Restriction (FDR; n=8), and Fatty-Exercise (FEX; n=9) groups. Original WBN/Kob (lean) rats were used as Control (C; n=6). The C and FOB rats had free access to food. FDR and FEX rats had food intake restricted to 69% and 70% of FOB, respectively. The FEX rats voluntarily ran on a rotary wheel ergometer for 6 weeks. Their running distance was 1711±458m/day. Soleus muscle tissues were prepared for transmission electron microscopy. Glut4, HK-Ⅱ, COX-Ⅳ and PCG-1α protein expression in soleus muscle were evaluated with the western blotting method.
RESULTS: Mean body weight, Homa-IR index, serum glucose, and serum triglyceride levels in FOB were significantly higher than C, FDR and FEX. Electron micrographs of soleus muscle fiber in FOB revealed ectopic deposition of lipid droplets and mitochondrial swelling within the myofibril. Chronic exercise combined with dietary restriction attenuated body-weight gain, increased the mass of soleus muscle and significantly reduced Homa-IR index, serum triglyceride and free-fatty acid levels compared with FOB and FDR. Furthermore,

Glut4, HK-II, COX-IV protein expression in soleus increased significantly in FEX compared with FOB and FDR. Soleus muscle fibers from FEX and FDR showed marked reduction of intracellular lipid droplets accumulation. However, dietary restriction alone in FDR increased the serum insulin level and Homa-IR index, and reduced the mass of soleus muscle compared with FEX.
CONCLUSION: Chronic exercise with dietary restriction improved ultrastructural abnormalities such as ectopic lipid accumulation, and metabolism in skeletal muscle. At least these changes associated with improvements of insulin resistance may contribute to prevent the development of diabetes in the WKF rat model of chronic pancreatitis and diabetes with obesity. The present results partly support the importance of habitual exercise in the prevention of diabetes with obesity.

ESSENTIAL OIL OF ALPINIA ZERUMBET REDUCES MUSCLE INJURY WITHOUT AFFECTING AUTOPHAGY RESPONSE IN RAT MUSCLE FOLLOWING ECCENTRIC EXERCISE

YU, H.F., WANG, D.C., LEE, Y.C.
KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION:Eccentric exercise causes muscle damage, including loss of strength, muscle soreness, and elevated plasma creatine kinase level. Damaged cytosolic elements are degraded and its constituents recycled to ensure cellular clearance and energy homeostasis through a process called autophagy, which is essential for the adaptation to training (1). The essential oil of Alpinia zerumbet (EOA) presents myorelaxant and antispasmodic actions on skeletal muscles (2). The purpose of this study is to investigate whether the intervention of EOA on muscle affect the muscle strength and the autophagy response after eccentric exercise in rat skeletal muscle.
METHODS: There were 24 mature male Sprague-Dawley rats randomized into 4 groups, including Control (C, n=8), essential oil of Alpinia zerumbet (EOA, n=8), Eccentric exercise (Ex, n=8), and Eccentric exercise+EOA (Ex-EOA, n=8). Essential oil of Alpinia zerumbet was applied to both quadriceps 30 min before eccentric exercise in EOA and Ex-EOA groups. Rats in the exercise groups (Ex and Ex-EOA) were challenged by 3-sessions of intermittent downhill running (15% decline) at progressive speed of 12 m/min, 18 m/min, and 25 m/min for 5 min with 2 min rest interval between each bout of running. After 24 h of the eccentric exercise, hind limb extensor thrust response was measured and then the blood and quadriceps muscle were collected for further analysis.
RESULTS: The score of hind limb extensor thrust response was impaired in Ex group ($p<0.05$) but not in Ex-EOA group. Plasma creatine kinase level, analyzed by enzyme-linked immunosorbent assay, was increased in Ex group ($p<0.001$). There was no significant difference of plasma creatine kinase level between C and Ex-EOA groups, indicating EOA treatment could maintain the integrity of myofibers after eccentric exercise. The biomarkers of autophagy response, including LC3 and Atg12, were increased in Ex and Ex-EOA groups ($p<0.05$ and $p<0.01$, respectively), indicating exercise-induced autophagy response was not affected by EOA treatment.
CONCLUSION: The essential oil of Alpinia zerumbet can prevent the decline of hind limb extensor thrust response after eccentric exercise through reducing muscle injury. Importantly, application of essential oil of Alpinia zerumbet does not affect autophagy response after eccentric exercise.

BLOOD-FLOW RESTRICTED EXERCISE AUGMENT ANABOLIC SIGNALLING COMPARABLE TO HIGH LOAD RESISTANCE TRAINING AND TRANSLATES INTO SIMILAR MUSCLE GROWTH DURING 9 WEEKS OF TRAINING

NÆSS, T.C.1, DAVIDS, C.2, MOEN, M.1, CUMMING, K.T.1, ROBERTS, L.2, RAASTAD, T.1
1. THE NORWEGIAN SCHOOL OF SPORTS SCIENCES 2. THE UNIVERSITY OF QUEENSLAND

INTRODUCTION:It is well established that high-load resistance training (HL-RT, >70%/1RM) activates mTORC1 and elevates muscle protein synthesis. In addition, evidence from the last decade point to the direction that lower mechanical loads (20-40%/1RM) combined with blood flow restriction (BFR) can activate mTORC1 and augment protein synthesis to a similar extent (1). The aforementioned are reflected in evidence supporting that RT with BFR (BFR-RT) has shown comparable effects on muscle hypertrophy compared to HL-RT (2). However, the molecular mechanisms undermining the increased muscle hypertrophy in response to BFR-RT are less known. Thus, we aim to elucidate some of the anabolic candidates regulating muscle hypertrophy induced by BFR-RT compared to HL-RT.
METHODS: 21 strength trained males/females (24±3y) were randomly allocated to perform 9 weeks of strength training (3/week) with either BFR-RT or HL-RT. Before and after the intervention, m. quadriceps cross-sectional area (CSA) was measured with magnetic resonance imaging (MRI), and maximal voluntary contraction (MVC) force of the knee extensors was assessed on an isokinetic dynamometer. Furthermore, the anabolic signalling responses to a single bout of exercise were assessed by obtaining muscle biopsies from m. vastus lateralis before, 2-, 24 -and 48 hours after the last exercise session. Muscle samples were analysed with western blotting for the phosphorylation responses of p70S6K, 4E-BP1, ERK1/2, and rpS6.
RESULTS: Quadriceps CSA increased with BFR-RT (6.8±4.3% .003) and HL-RT (4.7±2.9% .007) with no differences between groups (.296). HL-RT increased MVC (9.7±12.2% .030) while no changes was observed after BFR-RT (5.2±12.9% .28), no group interaction (.416). Phosphorylation of p70S6KThr389 was elevated from baseline at 2h (26±18% .008) and 24h (18 ±14% .018) in HL-RT and elevated at 2h (16±10% .001) in BFR-RT, with no differences between conditions (.826). Phosphorylation of rpS6Ser235/23 was not different between HL-RT and BFR-RT (.564). Moreover, there was no group difference in phosphorylation of 4E-BP1Thr37/46 (.474). Phosphorylation of ERK1/2Thr202/Tyr204 increased from baseline at 24h (3.2±2.6% .009) in HL-RT and increased from baseline at 2h (3.8±2.4% .002) and 24h (5.2±4.3% .011) in BFR-RT, with no differences between conditions (.563).
CONCLUSION: Overall, these data support the application of BFR-RT to induce hypertrophic adaptations comparable to HL-RT. In addition, our data suggests that the key anabolic signalling proteins driving the hypertrophic responses from BFR-RT and HL-RT are equivalently activated following an exercise bout of either training modalities. This suggests that the activation of the mTORC1 pathway along with ERK1/2 to be important as a potential underlying molecular mechanism of BFR-RT induced muscle hypertrophy. Consequently, BFR-RT could be used to reduce external mechanical loading while inducing a potent anabolic response proceeding to muscle hypertrophy.

ESSENTIAL OIL OF ALPINIA ZERUMBET REDUCES MUSCLE INJURY WITHOUT AFFECTING HEAT SHOCK PROTEIN EXPRESSION IN RAT SKELETAL MUSCLE FOLLOWING ECCENTRIC EXERCISE

CHEN, L.

KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION:Eccentric exercise induces muscle damage, as evidenced by increased muscle force loss, perceived muscle soreness, and elevated plasma creatine kinase level. Heat shock proteins (HSP) are stress inducible effectors and confer resistance to cellular stress and injury. Evidence indicates that eccentric exercise-induced HSP expression represents an important adaptive response in muscle subjected to stress (1). The essential oil of Alpinia zerumbet (EOA) presents myorelaxant and antispasmodic actions on skeletal muscles (2). This study aimed to determine the influence of essential oil of Alpinia zerumbet on muscle force, plasma creatine kinase, and HSP response to eccentric exercise in rat skeletal muscle.
METHODS: Mature male Sprague-Dawley rats were randomized into 4 groups: Control (C, n=8), essential oil of Alpinia zerumbet (EOA, n=8), Eccentric exercise (Ex, n=8), and Eccentric exercise+EOA (Ex-EOA, n=8). EOA was applied to both quadriceps 30 min before eccentric exercise. Rats in the exercise groups (Ex and Ex-EOA) were challenged by 3-sessions of intermittent downhill running (15% decline) at progressive speed of 12 m/min, 18 m/min, and 25 m/min for 5 min with 2 min rest interval between each bout of running. The hind limb extensor thrust response was measured 24 h after an acute bout of downhill running, which was followed by blood and quadriceps muscle collection.
RESULTS: The score of hind limb extensor thrust response was impaired in Ex group ($p<0.05$) but not in Ex-EOA group. Plasma creatine kinase level, analyzed by enzyme-linked immunosorbent assay, was 3.5 -fold greater than C group in Ex group ($p<0.001$). Meanwhile, there was no significant difference of plasma creatine kinase level between C and Ex-EOA groups. Moreover, the results of western blotting showed increased muscular HSP70 expression in Ex and Ex-EOA groups ($p<0.01$ and $p<0.05$, respectively).
CONCLUSION: Essential oil of Alpinia zerumbet reduces muscle injury following eccentric exercise. The increased HSP70 expression in skeletal muscle following eccentric exercise indicating that HSP play a role in skeletal muscle recovery and remodeling/adaptation processes. However, this response is unaffected by surface application of essential oil of Alpinia zerumbet.

ECCENTRIC EXERCISE ACTIVATES AUTOPHAGY IN ACHILLES TENDON OF ADULT MALE RATS

HSU, T.H., WANG, D.C., LEE, Y.C.

KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION:Eccentric exercise causes skeletal muscle damage, including loss of strength, muscle soreness, and elevated plasma creatine kinase level. Damaged cytosolic elements are degraded and its constituents recycled to ensure cellular clearance and energy homeostasis through a process called autophagy, which is essential for the adaptation to training (1). Eccentric training is usually used in clinical environment to rehabilitate patients with tendon injury (2). In this context, eccentric training is supposed to induce autophagy in tendon remains unclear. The aim of this study was to determine the effect of acute eccentric exercise on autophagy response in tendon of adult male rats.
METHODS: The mature male Sprague-Dawley rats were divided into 2 groups: Control (C, n=8) and Eccentric exercise (E, n=8). E group was challenged by 3-sessions of intermittent downhill running (15% decline) at progressive speed of 12 m/min, 18 m/min, and 25 m/min for 5 min with 2 min rest interval between each bout of running. After 24 h of the eccentric exercise, hind limb extensor thrust response was measured and then the blood and Achilles tendon were collected for further analysis.
RESULTS: The score of hind limb extensor thrust response was impaired in E group ($p<0.05$). Plasma creatine kinase level, analyzed by enzyme-linked immunosorbent assay, was increased in E group ($p<0.001$). The biomarkers of autophagy response, including LC3 and Atg12, were increased in E group ($p<0.001$ in both biomarkers), indicating eccentric exercise-induced autophagy response was observed in E group. Meanwhile, plasma creatine kinase level showed a strong correlation with LC3 ($r=0.628$, $p<0.01$) and Atg12 ($r=0.716$, $p<0.005$).
CONCLUSION: The results show that acute eccentric exercise provoke autophagy in Achilles tendon of adult rats, which is correlated to muscle injury. Because autophagy plays a protective role in preventing fibrosis after tendon injury (3), our data provides evidence showing that autophagy may play a role in tendon adaptation to eccentric exercise.

THE IMPACT OF HIGH-INTENSITY INTERVAL TRAINING ON FUNCTIONAL CHARACTERIZATION OF SHORT-TERM PERIPHERAL CD4 T-CELL ACTIVATION IN SEDENTARY MEN

TSAI, H.H., WANG, J.S.

CHANG GUNG UNIVERSITY

INTRODUCTION:The volume and intensity of exercise can have significant effects upon the function of leukocytes. The purpose of this study was to investigate the effects of high-intensity interval training (HIIT) and moderate-intensity continuous training (MICT) on the characteristics of several intracellular activation processes during short-term activation of CD4 T-cells.
METHODS: Twenty-four sedentary males were randomized to perform either HIIT (3-minute intervals at 40% and 80%VO2max, n=12) or MICT (sustained 60%VO2max, n=12) for 30 minutes/day, 5 days/week for 6 weeks. At rest and immediately after maximal exercise test, cytoplasmic Ca2+ level, mitochondrial Ca2+ level, reactive oxygen species (ROS), and nitric oxide (NO) generation in CD4 T-Cell were measured by flow cytometry.
RESULTS: The experimental results demonstrated that acute exercise increased cytoplasmic Ca2+ level in CD4 T-Cell before the HIIT or MICT regimen. Cytoplasmic Ca2+ level in CD4 T-Cell in HIIT were lower than that in MICT. Furthermore, both of HIIT and MICT could decline ROS in CD4 T-Cell significantly. The extent of NO generation and the level of mitochondrial Ca2+ were not altered at any time during our study.
CONCLUSION: We conclude that HIIT is superior to MICT for modulating function of short-term peripheral CD4 T-Cell activation. This may alter the behavior of CD4 T-cells during activation.

Motor Learning and Motor control

EFFECT OF RAKET SPORTS RETENTION TO TRANSFER PERFORMANCE IN STUDENT

SATO, T., NAKAJIMA, M., WATANABE, E.

JISSEN WOMENS UNIVERSITY

INTRODUCTION:Everybody readily asserts that people can still ride a bicycle after many years without practice. The motor system with retention is highly redundant the almost likely tasl can always be accomplished by many different sequences of motor commands [Bernstein, 1967]. A many years without practice study of multivariable behavior naturally raise the question of which reference frames the central nervous system may use to coordinate motor actions. Previous studies were focused planar reaching movements and showed that translation and rotation of the start and target positions evoked joint kinematics.
In Japan, we have ministry's curriculum guideline for all forced education of course study. However, it was not described detail to play specific sports.
This investigation of the retention at highly skilled motor performance about tennis racket simple task by findings from arm hand motor behavior. Moreover, it were applied tennis and badminton educational program and extra lesson for acquired physical education in Japanese schools.
METHODS: Seven healthy female university students with a mean ± SD age 21.29 ± 0.89 years, volunteered to participate in the study. The protocol was explained and subjects gave the informed consent prior to the participation in this study. Two subjects were physically activity in additionally they had experiment tennis and badminton in childhood. All subjects had abstained from alcohol, caffeine and exercise for 24 hours preceding the investigation to ensure reliability.
They had performed to encage which has distance 4m by same tennis racket until 2000 times trials. And the sensor device of three dimensional which recorded accelerometer with sampling 100Hz put on top their grip of their racket during swing
RESULTS: The two retention player were rapidly increased encage goal by racket(Fig.2).
There were significant difference between subject with retention and novice. It was observed clearly motion skills to control tennis racket by badminton player. It was illustrated typical experience curve for all subjects. However there were rapidly increaseing goal sucsessful swing for raket sports retention. There were no significant differnece impact a ball by raket asacceleration for retention subjects from initial to end condtion.
CONCLUSION: We examined three dimensions accelerometer and true-false simple racket shot in tennis until 2000 times, major found that the retention has been acquired in two subjects. However all subjects had appeared learning-curve over 200 trials, especially in a short amount of time more than continued long-winded trails until 2000 times. It was appeared that once acquired similarity motor skills were retention as same as badminton and tennis. It was consider that motor control skills under age applied similarity retention of motor learning.

INFLUENCE OF FORCE OR NEURAL FEEDBACK ON NEURO-MECHANICAL VARIABLES

CUDICIO, A., COGLIATI, M., NEGRO, F., ORIZIO, C.

UNIVERSITY OF BRESCIA

INTRODUCTION:The force modulation during static increasing (ON)/decreasing (OFF) force ramps depends on the combined levels of motor unit (MU) recruitment and firing rate. During OFF, the MU neural control is not the mirror image of the one adopted during ON (1). The use of the neural feedback (NF) can be helpful to understand in depth the relationship between neural patterns and force output control in particular during OFF.
METHODS: First dorsal interosseous muscle (FDI) of nineteen subjects (8 women and 11 men, age 22±2) was investigated. The individuals sat with the forearm of their dominant limb positioned in a dedicated ergometer. The FDI force signal was recorded using a 50 N load cell mechanically coupled with the second phalanx of the index finger detecting the generated tension along the sagittal plane during static abduction. The EMG signal was picked-up using two electrodes placed on the FDI muscle belly, after proper skin preparation.
Protocol 1 – force feedback (FF). After MVC evaluation the subjects performed a 0-50-0% MVC force triangle. The slope of the ramp was 6.6 %MVC/s in order to avoid fatigue. Protocol 2 – NF. Similarly, the subjects performed a 0-50-0 % EMGmax envelope triangle. In this case the NF was obtained from the EMG rectification and low pass filtering (cut off frequency 5 Hz). In both protocols the recorded force and EMG envelope acted alternatively as master and slave signals according with the performed FF or NF protocol.
Thus, a hysteresis factor (H) has been calculated as the relative ratio between the areas under the signal in OFF and ON phases for both the master or slave signal. The obtained value was 100% in case the OFF signal mirrored the ON signal, >100% or <100% if the OFF area resulted greater or lower than ON area, respectively.
Two way repeated measure ANOVA was used to compare H values of master and slave signals in the two conditions; Tukey test was used for the post hoc analysis.
RESULTS: The comparison of the H of the force and of the EMG envelope signals showed differences when their values from protocol 1 and 2 were compared ($P<0.001$). H values for master signals were always close to 100 independently from the protocol 1 or 2. Otherwise, the slave signal presented H values strongly dependent on FF or NF condition: in the first case H<100% with a reduction of the EMG activity during OFF, in the second one H>100% suggesting an extra force production during OFF.
CONCLUSION: The evident tension overproduction during NF OFF suggests that in motor control system the relationship between the mechanical output and the level of neural activation is not well represented. This may be due to the underestimation of the MU contractile efficiency improvement after their activation during ON phase.

COMPARISON OF SCAPULAR MUSCLE RECRUITMENT PATTERNS AMONG VARIOUS TYPES OF BASEBALL PITCHES IN HIGH SCHOOL PITCHERS

TSAI, Y.S., CHU, C.H., CHEN, W.T., CHANG, C.C.

UNIVERSITY OF TAIPEI

INTRODUCTION:Shoulder and elbow injury rates were reported to be associated with various types of baseball pitches. Scapular stability plays an important role during pitching that may affect the performance of shoulder and elbow joint. However, it is not clear whether

there are differences in scapular muscle recruitment patterns among various types of baseball pitches. In this study, we compared scapular muscle activations during each phase of pitching among various types of baseball pitches in high school pitchers.
METHODS: Scapular muscle activities (upper trapezius [UT], lower trapezius [LT], and serratus anterior [SA]) were measured for 10 healthy high school pitchers throwing fastballs, curveballs, change-ups, and sliders in an indoor biomechanics laboratory with a wireless electromyography (EMG) system. A high-speed camera system was used for defining pitching phases (wind-up, stride, arm cocking, and arm acceleration phase) analyzed in this study. Peak and average EMG amplitude (%maximum voluntary contractions [MVC]) of each scapular muscle in each phase of pitching were selected for comparing the differences among the 4 types of pitches and among the different phases of pitching.
RESULTS: Among the 4 types of pitches, there were no significant differences in both peak and average EMG amplitude of each scapular muscle during each phase of pitching. The differences of muscle activities in scapular muscles only existed among different phases of pitching in all pitch types. In the aspect of average EMG amplitude, both LT and SA had greater values in the arm cocking phase and arm acceleration phase compared to the stride phase in all pitch types. Both LT and SA also had greater average EMG amplitude in the arm acceleration phase compared to the arm cocking phase while throwing sliders. In addition, SA had greater average EMG amplitude in the arm acceleration phase compared to the arm cocking phase while throwing curveballs. In the aspect of peak EMG amplitude, SA had greater values in the arm cocking phase and acceleration phase compared to the stride phase in all pitch types. LT demonstrated greater peak EMG amplitude in the arm cocking phase and acceleration phase compared to the stride phase while throwing sliders.
CONCLUSION: Scapular muscle recruitment patterns among various types of baseball pitches were similar. This may mean that the scapular stability required for all types of pitches is the same. LT and SA muscle activities increased from stride phase to the arm cocking phase and acceleration phase during pitching.

THE DEVELOPMENTAL CHARACTERISTICS OF THE HOPPING MOVEMENT IN PRESCHOOL CHILDREN

SASAKI, R.1, ISHIZAWA, J.2

1: KEIO UNIVERSITY, 2: SHIRAYURI UNIVERSITY

INTRODUCTION:Among fundamental motor skills, hopping is one of the distinctive skills humans adopt to accomplish the important task of upright locomotion (Whitall, 2003). Hopping is a rhythmically cyclic movement requiring significant muscle strength, multi-limb coordination, and dynamic balance to be performed proficiently. Typically developing children begin to perform hopping around the age of three and improve during early and middle childhood. In this study, we clarified the developmental changes of motor coordination, focusing on movement patterns of legs and arms during hopping in preschool children.
METHODS: Participants were typically developing children, 58 boys and girls aged 4-6 years. They were asked to perform two tasks, hopping on their preferred and their non-preferred foot, on an approximately 5-m pathway. Before each trial, a mature hopping movement was demonstrated until they understood the task. We filmed and analyzed all of their movements, then observationally evaluated children's movements according to the criteria of a previous study (Halverson and Williams, 1985). We focused on the developmental movement levels of lower and upper extremities during hopping sequences. Developmental levels were compared across age groups.
RESULTS: The observational evaluation of leg and arm action found that the rate of the lower level (step 2) decreased and that of the intermediate level (step 3 and 4) increased with age. Comparing hopping on the preferred and non-preferred leg, many children were at a lower developmental level when hopping on their non-preferred leg. About 30% of the younger group were evaluated at the lowest level (step 1) when hopping on their non-preferred leg. Girls, particularly older ones, tended to be developmentally ahead of boys in hopping movement.
CONCLUSION: Overall, hopping performance improved with age in 4–6-year-old children. The developmental changes of their movements involved their lower and upper extremities gradually advancing from passive, reactive leg and arm movements to active assistance in the development of hopping force. The developmental sequence of leg and arm action was almost the same whether the preferred or non-preferred leg was used for hopping; however, the non-preferred leg lagged developmentally.
In conclusion, consistent with previous research (Halverson and Williams, 1985), preschool should be regarded as the period children progress from the rudimentary to intermediate level in hopping movement.

THE DEVELOPMENT OF NEUROMUSCULAR COORDINATION IN GYMNASTS DURING LANDINGS

NIESPODZINSKI, B.1, GRAD, R.2, MIESZKOWSKI, J.2, KOCHANOWICZ, A.2

1- KAZIMIERZ WIELKI UNIVERSITY, BYDGOSZCZ; 2- GDANSK UNIVERSITY OF PHYSICAL EDUCATION AND SPORT, GDANSK

INTRODUCTION:The topic of landings in gymnastic sports is very important due to many injuries, and it has been repeatedly discussed, especially using kinematic and dynamic analyses (1). However, there is limited insight into the activity of individual muscles during landings and the development of neuromuscular coordination of gymnasts in comparison to non-athletes (2). The aim of the study was to evaluate the differences in the surface electromyography (SEMG) of muscles involved in landings between participants representing three subsequent stages of gymnastics training and age-matched non-athletes.
METHODS: One hundred and four male subjects performed a counter movement jump (CMJ) on a force plate with simultaneous EMG recording. The groups of gymnasts were represented by 20 boys at the age of 8-10 years, 15 boys at the age of 12-14 years and 11 young adults, while the non-athletes groups comprised 22, 19 and 17 age-matched individuals. The following time periods were analyzed: 100 ms before contact (BC) with the force plate, first (AC1) and subsequent 100 ms after contact (AC2). The recorded ground reaction forces (GRF) and the SEMG amplitudes were normalized to the body weight and the maximal voluntary contraction, respectively.
RESULTS: The youngest gymnasts showed 33% higher peak GRF in comparison to corresponding non-athletes ($P<0.05$) and also to older (12-14 years) participants ($P<0.05$). Moreover, the time to peak GRF in the youngest gymnasts was the shortest among all participants. In the AC1 period, gymnasts showed a 28% higher rate of GRF than non-athletes ($P<0.05$), while the outcome in AC2 was opposite, with a 46% higher rate of GRF in non-athletes ($P<0.05$). The SEMG analysis showed that almost in all analyzed cases muscle activity amplitude was higher in non-athletes in BC, regardless of age. In the case of rectus femoris, only the youngest gymnasts had 33% lower SEMG activity ($P<0.05$), while older gymnasts in comparison to non-athletes had higher activity. In the tibialis anterior there were no differences within particular age groups. In subsequent AC1 and AC2 periods, the SEMG activity increased similarly in every group.

CONCLUSION: Long-term gymnastic training causes specific muscle adaptations visible during landings. Gymnasts surpass their peers in the CMJ performance; however, in the youngest gymnasts the consequential GRF indicate higher musculoskeletal loading and thus an increased risk of injury. The decreased level of rectus femoris activity may be associated with these findings.

MRCP INDUCED BY BUTTON PUSHING IN RESPONSE TO BADMINTON VIDEO CLIP

SUDA, K., FUMOTO, M., USUI, S., NISHIHIRA, Y.
TOKYO INSTITUTE OF TECHNOLOGY

INTRODUCTION:Brain wave, especially event related potentials (ERPs) have been used for studying the activity of the brain during sports as well as various human activities. Because ERPs are very small electrical changes, averaging is necessary to measure. In sports, exactly the same situation never happens. We have been using video clips to measure ERPs during badminton play. This enable us to measure ERPs during sports. MRCP (motor related cortical potentials) is one of the ERPs which can be recorded just before movement (1). With this potential, readiness of movements can be compared. In badminton, the flight time of the shuttlecock is various, it is not known when the players begin to prepare for hitting the shuttlecock. Therefore, by the MRCP, we tried to get some information about the time that the brain begins to activate for hitting.
METHODS: Badminton video clip were made for the experiment. In the video clip, the player on the right side made long high service to the left side player. The left side player made smash, drop or clear. Then the right side player hit the shuttlecock. The participants were asked to push the button at the time the right side player hit the shuttlecock. EEG was recorded from 12 electrodes including C3, Cz, C4 according to the international 10-20 method. The participants watched video clips and responded to the smash, drop and clear video clips for 45 times respectively, Electrooculogram was also recorded to detect artifact and averaging was done for the trials without artifact. Electrical signal at the pushing button was used for the trigger of the averaging.
RESULTS: The amplitude of the MRCP was largest in Cz. This result suggest Cz was most active location and was in accordance with the previous studies. The amplitude from C3 was larger than the one from C4. All participants were right handed and they pressed the button by the right thumb. This also in accordance with the previous studies and considered that C3 reflects activation of primary motor cortex for the right finger. The amplitude of MRCP to the smash receive tended to be larger than other two conditions. This suggests that players' motor related cortex is more activated when receiving smash than other flights. And the onset of MRCP in smash receiving tended to be earlier than other flights. This suggests preparation for smash receive begin earlier than other flights.
CONCLUSION: Overall, these data suggest that preparation of motor related cortex depends on the flight from the opponent in this study.

INFLUENCE OF VISUAL DISTURBANCE ON POSTURAL CONTROL

AOI, M.
KYOTO UNIVERSITY

INTRODUCTION:When learning a new exercise, the internal model of the brain is updated based on the error information and the appropriate exercise commands can be generated. Human quiet standing depends on modifications to internal models as well as corrections by operating feedback information. However, it is not yet clear how the brain adapts postural control mechanism to various environments by integrating sensory information. In my research, I clarify how the internal model reflecting the relationship between visual information and exercise in postural control is modified and examine the effect of a new internal model.
METHODS: Healthy subjects performed a visual tracking task to make their center of pressure (CoP) displayed on the screen of the head mounted display follow the target. In the middle of the task, the visual rotation disturbance such that the CoP position displayed on the screen rotates counterclockwise from the actual CoP position was given and the correction process was quantified. Cursor clamp trials were performed to fix the CoP position on the straight line in the front and back direction and error quantified as the amount of modification induced by feedforward model. The CoP position calculated from vertical components of the ground reaction force.
RESULTS: The trajectory of CoP position during the task tilted toward the disturbance. In the cursor clamp trials, the trajectory of CoP position during the task tilted toward the disturbance. Postural control was not affected by visual disturbance.
CONCLUSION: This result suggests that the internal model that converts visual information into exercise was updated by the tracking task.

LEARNING EXPECTANCIES DIFFERENTIATLLY INFLUENCE SKILL EXECUTION UNDER DISTRACTION AND STRESS: EXPLORING THE OPTIMAL THEORY.

SIMMONDS, P., ROBERTS, J.W.
LIVERPOOL HOPE UNIVERSITY

INTRODUCTION:The long-standing view of a positive relation between enhanced expectancies and motor learning outcomes has been elaborated on by the OPTIMAL theory (1). Indeed, it is suggested that enhanced expectancies contribute to the formation of stimulus-response links that engender automatic control processes. The following study aims to examine this framework, including responses to stress-induced self-focus and secondary task distraction under different learning expectancies.
METHODS: Thirty participants were equally distributed into learning groups: enhanced expectancies (EE), reduced expectancies (RE) and control (CTL). Each participant was scored on a novel dart-throwing task at baseline/pre-test and practice, which additionally featured large or small concentric circles surrounding the intended bullseye (top score) (2). While retaining the intention to reach a top score, the EE group were instructed that a successfull shot required hitting the large circle, although the RE group were instructed a successful shot required hitting the small circle. The CTL group were provided no additional instructions. Participants returned a day later to complete a 24-hr retention test, stress and dual-task transfer tests. Stress transfer involved a combination of a social evaluative threat and negative false-performance feedback. Dual-task transfer involved a tone-counting task whilst executing the dart throw. Total error scores from the throws were analysed using a two-way mixed-design ANOVA (Day 1:3 group[EE,RE,CTL]x6 block[baseline,1-5]; Day 2:3 group[EE,RE,CTL]x3 test [retention,stress,dual]).
RESULTS: Efficacy and stress manipulation checks revealed responses that were consistent with the nature of the instructions. Total error scores on Day 1 showed no significant difference in the learning outcomes between groups (P>.05). However, the analysis on Day 2

revealed a significant interaction between group and test (P<.05). Post hoc analyses indicated significantly more error for RE compared to EE and CTL in the dual-task transfer, although more error was found for EE compared to RE and CTL in the stress transfer (Ps<.05).
CONCLUSION: While unable to reflect the learning advantage served by enhanced expectancies, the present findings allude to dissociable sensorimotor processes as a function of learning expectancies. That is, enhanced expectancies engender automatic control, which accommodates performance under distraction, but attenuates it under stress-induced self-focus. These findings provide at least some support for the OPTIMAL theory.

INFLUENCE OF FORCE CONTROLLED SUSTAINED SUBMAXIMAL TEETH CLENCHING ON UNIPEDAL STANCE

ISSELÉE, H., DE VROEY, H., VANRENTERGHEM, J., DE LAAT, A.
KU LEUVEN - UNIVERSITY OF LEUVEN

INTRODUCTION:Teeth clenching or bruxism may occur under circumstances of high level physical activity or as a sign of psycho-emotional stress during sports, work and daily activities (1). It has been suggested that afferent signals from the masticatory system contribute to balance control (2). This may be supported by the existence of reciprocal neuronal connections in the brainstem, altered sympathetic activity or interactions with cervical muscles. In the present study we investigated the extent to which submaximal clenching in unipedal stance has an impact on postural control.
METHODS: Ten healthy subjects (5 females – 5 males) aged 20 - 23 years were recruited among physiotherapy students. Included subjects were free of temporomandibular, oral or musculoskeletal disorders. In a random order they all performed two trials of unipedal stance on a force platform (AMTI, Watertown MA, USA). Anterior-posterior (AP) and medio-lateral centre of pressure (COP) position and COP path length were analysed. Bite force was continuously monitored by means of a custom made bite sensor (Loadstarsensors, Fremont CA, USA) placed between the 2nd molars. One trial involved a sequence of 10s controlled non-biting, thereafter subjects were instructed to bite for 30s with a bite force that is equal to 20 % of their individual maximal clenching force based on realtime feedback. The other trial, which served as a baseline measure, involved a 40s non-biting condition.
RESULTS: Statistical analysis showed a significant difference for average anterior-posterior COP position between the first 8 seconds and last 8 seconds within the submaximal clenching trial ($p = 0.026$). This could not be found in the non-clenching trial when using the same time-units. When comparing the mean AP COP position between the non-clenching trial and the submaximal clenching trial during 20 s, the anterior deviation occurred as well ($p = 0.085$) but did not reach statistical significance ($p > 0.05$). No significant differences were found for other postural balance parameters.
CONCLUSION: Sustained submaximal isometric clenching was associated with a forward displacement of the body's centre of pressure in unipedal stance. Future research should focus on the underlying mechanisms through which bruxism influences postural balance and movements as it appears that sustained clenching is associated with an altered postural control.

THE POSITIVE INFLUENCE OF A TWELVE-WEEK MILO ® SPORTS CAMP PROGRAM ON MOTOR SKILL DEVELOPMENT AND PSYCHOSOCIAL SKILLS IN SCHOOL-AGED CHILDREN

COSTELLO, S., SAUVAGEOT, N., GENTILE-RAPINETT, G.
NESTLE INSTITUTE OF HEALTH SCIENCE

INTRODUCTION:Promoting the development of motor skills at a young age has been purported to contribute to children's physical, cognitive and social development and is suggested to provide the foundation for an active lifestyle. Of recent there has been particular interest in the additional psychosocial benefits associated with motor skill development and methods by which they can be developed. The purpose of this study was to assess the impact of a twelve-week sports soccer program on school-aged children's motor skills, soccer-specific skills and psychosocial skills including self-perception, perceived competence and mood.
METHODS: Eighty-six children (mean ± SD age 8.5 ± 1.1; height 131.6 ± 7.7cm; weight 30.4.± 8.5kg) were recruited from 12 MILO® sports camps in different regions across Thailand and completed 6-8 hours of soccer skill practice on weekends. General motor skills including locomotor skills and object control were assessed prior to and following the twelve-week sports camp in addition to perceived competence, mood and ratings of self-efficacy.
RESULTS: Analysis indicated a significant improvement in total gross motor development score ($p<0.001$) in addition to individual motor-skills including; running ($p<0.001$), galloping ($p<0.001$), hopping ($p<0.05$), stationary dribble ($p<0.005$) and kick ($p=0.001$). Data analysis also revealed positive changes in self-perception ($p<0.005$) as well as sub-parameters contributing to self-perception, namely athletic competence ($p=0.002$) and global self-worth ($p=0.01$). No improvements were observed in mood as measured by the Profile of Mood States.
CONCLUSION: These findings highlight that the potential benefits of regular participation in team sports extend beyond those that are solely health-related. A twelve-week sports camp may provide an effective means for contributing towards motor skill development as well as children's psychosocial skills including self-perception, perceived competency and self-worth.

Neuromuscular Physiology

EFFECTS OF ISOKINETIC AND ISOMETRIC CONTRACTION BY ECCENTRIC EXERCISE-INDUCED MUSCLE DAMAGE FOR LOWER EXTREMITIES ON ELECTROMYOGRAPHIC

CHUANG, C.T.1, LAI, J.H.1, CHEN, H.L.1, LIN, M.J.1, CHEN, T.C.C.2
DEPARTMENT OF PHYSICAL EDUCATION, HEALTH AND RECREATION,NATIONAL CHIAYI UNIVERSITY,CHIAYI,TAIWAN,DEPARTMENT OF PHYSICAL EDUCATION.NATIONAL TAIWAN NORMAL UNIVERSITY,TAIPEI CITY,TAIWAN

INTRODUCTION:To the best of our knowledge, only two studies compared the degree of eccentric exercise-induced muscle damage (EIMD) for two leg muscle groups (knee extensor, KE and knee flexor, KF) in the lower extremities (1) (2). The results consistently found that the degree of damage of KF was significantly greater than that of KE. However, neither of the above two literatures discussed the electromyographic (EMG) responses and couldnt know the neurological adaptation.

METHODS: Sixteen healthy young untrained men were placed into the KE (KE group) and KF (KF group) (n=8/group) based on the baseline maximal concentric isokinetic strength (MVC-CON). The KE and KF groups performed 60 times of maximal eccentric contractions (MaxECC, 30°/s) with non-dominant leg extensor (KE group) or flexor (KF group) muscles . Maximal isometric muscle strength (MVIC), MVC-CON, muscle soreness (MS), rang of motion (ROM), mean power frequency (MPF), and root mean square (RMS) were measured on the 0th to 5th days before and after MaxECC.
RESULTS: All measures of Muscle Damage (MVIC、MVC-CON、MS、ROM), changes in the KF group was significantly greater than the KE group (p<.05). Changes in MPF and RMS were significantly greater for MVIC than MVC-CON of the KF group. was (p<.05), but there was no significant difference between KE (p>.05). The MVIC of the KF group was significantly greater than that of the KE group (p<.05), but there was no significant difference between the MVC-CON (p>.05)。
CONCLUSION: These results suggest that the degree of KF muscle damage in humans is significantly greater than that of KE, and the same phenomenon is seen in the EMG. In the EMG
responses at different muscle strength tests, the static MVIC test at KF has significant
changes for the dynamic MVC-CON test. The EMG responses during static MVIC
test may be used as an indicator to effectively assess muscle damage.

LOWER LIMB EMG ACTIVITIES IN DIFFERENT PHASES OF SPRINT RUNNING PERFORMANCE

OKKONEN, O.1, CAZZOLA, D.1, SALO, A.I.T.2,1, COLYER, S.L.1
1: UNIVERSITY OF BATH, 2: KIHU - RESEARCH INSTITUTE FOR OLYMPIC SPORTS

INTRODUCTION:Electromyographic (EMG) signals have been analysed from different phases of sprint running performance, however, studies have usually concentrated only on one phase (e.g. sprint start [2]) or analysed only small number of muscles (1). Thus, this study compared EMG activities recorded for a single athlete across different phases of sprinting to understand the potential roles of different lower limb muscles across a sprint.
METHODS: One male sprinter (100 m: 10.33 s) performed two trials in each phase (start, acceleration [acc], maximum velocity [maxvel]) and EMG data were collected using wireless surface EMG sensors from eight lower limb muscles (gluteus maximus [GMAX], biceps femoris [BF], semitendinosus [ST], gastrocnemius medialis [GASTM], tensor fasciae latae [TFL], rectus femoris [RF], vastus lateralis [VL], and vastus medialis [VM]) of the rear leg in the starting blocks. From the normalised EMG signals, peak EMG and average EMG (aEMG) values were analysed for each phase (start: 1st step; acc: 7th step; maxvel: step at ~45-m mark) for the whole gait cycle (GC).
RESULTS: The highest peak EMGs for the GMAX (0.952 ± 0.068), TFL (0.891 ± 0.154), RF (0.917 ± 0.117), VL (0.871 ± 0.182), VM (0.890 ± 0.156) were measured during the start GC. For the GMAX, VL, and VM these peaks were produced during contact phase of the GC and for the TFL and RF during early swing phase of the GC. Especially for the VL and VM the peak EMGs were substantially larger than during the contact phase of the acc (VL: 0.576 ± 0.037; VM: 0.264 ± 0.047) and maxvel (VL: 0.482 ± 0.026; VM: 0.270 ± 0.107). The highest peak EMG for BF (0.940 ± 0.084) was achieved in the contact phase of the acc, however, the highest aEMG for the BF (0.475 ± 0.004) was measured in the contact phase of the maxvel. In addition, the highest peak EMG of the BF (0.620 ± 0.029) during the (late) swing phase was achieved during the maxvel. The highest peak EMGs for the ST (0.900 ± 0.142) and GASTM (0.83 ± 0.235) were measured in maxvel (late swing and contact phase, respectively). For the GMAX, the highest aEMGs were produced in the contact phase of the start (0.369 ± 0.023) and acc (0.383 ± 0.067), whereas the highest contact phase aEMGs for the ST were achieved during the acc (0.330 ± 0.007) and maxvel (0.281 ± 0.006).
CONCLUSION: The GMAX seems to have a considerable role during the contact phase in the start and acc. The higher VL and VM activity during the start could indicate the important role of these muscles in the start. The activity of the BF and ST seem to increase, both in the contact and late swing phase (especially in maxvel), as running velocity increases, indicating that their role as hip extensors increase in contact phase and that higher hamstring activity is needed in late swing in maxvel possibly to decelerate the faster knee extension motion.

Nutrition

EATING HEALTHY OR EATING TO WIN? WHAT BRAZILIAN AND SPANISH ATHLETES HAVE TO SAY ABOUT IT

JUZWIAK, C.
UNIVERSIDADE FEDERAL DE SAO PAULO

INTRODUCTION:According to the state-of-the-art sports recommendations, nutrition should be adjusted by taking into consideration athletes' individual goals and needs. However, eating practices reflect a complexity of factors including what athletes know, how they perceive food and what it represents.
METHODS: Using a qualitative approach, through recorded in-depth interviews, 66 amateur and semi-professional athletes (28 Brazilians and 38 Spaniards; 15-42 years old) from different sports (aesthetics, martial arts – MA, and team sports) were interviewed about their conception of "healthy eating", "athletic diet" and their eating practices. Verbatim transcriptions were analyzed through the Content Analysis method.
RESULTS: Regardless of the country, age or sport, for most athletes a healthy diet is also what they consider as adequate for optimal athletic performance. For Brazilians the most important aspects of "healthy eating" was to eat every 3-hours, and increased intake of fruits, vegetables and whole-grain foods, while Spaniards referred to a varied diet, and an increased intake of fish and legumes. In both countries, regardless of sport, healthy eating implied excluding ultraprocessed and fast foods, which are nevertheless valued on special occasions, such as a reward for victories/defeats. For most aesthetics and MA Brazilian athletes, the concept of an "athletic diet" is related to strict food control, also expressed as "diet with rules", revealing a gap between the practices they adopt (i.e. restriction of food/food groups), and what they understand as an adequate diet. Some athletes attributed special value to some foods at the competitive moment, indicating food beliefs. Brazilian MA athletes gave especial value to supplements as part of an "athletic diet". In addition to their conceptions, eating practices depend on other factors such as schedule, food and time availability, culinary skills, their identity as an athlete, and with whom they eat.

CONCLUSION: A mismatch was observed between athletes' conceptions, eating practices and sports recommendations. The conceptions about "healthy eating" and "athletic diet" reinforce the role of the cultural aspects of each country in defining what is adequate or not. Eating practice is influenced by these conceptions but by other factors as well. Contradiction between conceptions and practices were present especially when they follow restricted diets, when food is sought as a source of pleasure or when manifesting a belief. Understanding these mismatches is important for the nutritionists practice, since it can contribute to the development of effective educational strategies. It is necessary to broaden the understanding about how athletes think through an interdisciplinary approach, exploring meanings and representations about food, values attributed, how they organize information and how they apply these to their eating practices.

MULTIVARIATE STUDY ON DIETARY HABITS INFLUENCING DEGREE OF SATISFACTION WITH DIETING IN YOUNG ADULTHOOD

AOYAGI, O.1, SAKAGUCHI, H.2, ANNOURA, T.2, SAKAGUCHI, S.3

1. FUKUOKA UNIVERSITY, JAPAN, 2. JAPAN UNIVERSITY OF ECONOMICS, 3. FUKUOKA SEISHU HOSPITAL, JAPAN.

INTRODUCTION:Various factors such as with whom, what foods, how much, and when people eat impact the satisfaction with their dieting. In addition, the various factors were reasonably thought to be interrelated and the impact on satisfaction does not seem to emerge independently by itself. In summary, to examine the unique impact of each dietary habit on satisfaction, we must also statistically make the influence of other dietary habits constant. Thus, this study investigates dietary habits influencing degree of satisfaction with dieting in young adulthood by using Quantification Theory Type One (QTTO), which is one of the multivariate analyses treating multiple variables simultaneously.
METHODS: The questionnaire contained 13 items like "With whom did you eat dinner?" "What did you eat for dinner?" and "What time did you eat dinner?" In addition, respondents were questioned about their degree of satisfaction with dieting at the present day, using a 5-level scale from "very satisfied" to "not satisfied at all." A questionnaire survey concerning dietary habits at the present day was conducted with 858 Japanese N-university male students in September 2017. Then, QTTO was conducted using the degree of satisfaction as a dependent variable and dietary habits as independent variables. The extent to which the dietary habits impact the degree of satisfaction is examined using multiple correlation coefficients (MC), partial correlation coefficients (PC), and the range of category weights (RCW).
RESULTS: The results of QTTO for young adults showed the moderately high MC with R = 0.447. The independent variables indicating both high PC greater than 0.15 and RCW greater than 0.5 were "How frequently did you go to a convenience store or supermarket for food? (PC = 0.179, RCW = 0.769)," "With whom did you eat breakfast? (PC = 0.172, RCW = 1.208)" and "What did you eat for dinner? (PC = 0.152, RCW = .877)." Categories showing high contribution for satisfaction amongst independent variables showing high PCs and RCWs were "Once per week (Category weight [CW] = -0.402) in "How frequently did you go to a convenience store or supermarket for food?", "With parents (CW = -0.205)" in "With whom did you eat breakfast?" and "Rice (CW = -0.338) in "What did you eat for dinner?"
CONCLUSION: In conclusion, it is thought that their satisfaction with dieting was improved by eating with parents at breakfast and dinner, and that there is no concern about with whom to eat but what to eat is important. By growing up to young adulthood, they can get to freely choose favorite foods to eat so that their satisfaction is enhanced by going to convenience stores with a suitable frequency and choosing their favorite foods.

EFFECT OF ORAL RESVERATROL SUPPLEMENTATION ON OXIDATIVE STRESS, INFLAMMATION, EXERCISE-INDUCED FATIGUE AND ENDURANCE PERFORMANCE IN YOUNG ATHLETES

CHENG, I.S., TU, C.Y., LIN, H.C., LU, Y.C.

NATIONAL TAICHUNG UNIVERSITY OF EDUCATION

INTRODUCTION:Previous studies demonstrated that resveratrol (RES) can enhance antioxidant, anti-inflammatory and insulin actions in mice and humans (1,2). Wu et al., demonstrated that resveratrol supplementation protects against physical fatigue and improves exercise performance in mice. Their results in animal study showed significant increase in energy utilization and decrease in serum levels related fatigue makers under exhaustive swimming challenge after 21-d resveratrol supplementation (3). However, it is not thoroughly investigated whether resveratrol could serve as ergogenic aids for sport competition in athletes. Therefore, our study aimed to investigate whether oral resveratrol supplementation could blunt oxidative stress, inflammation, exercise-induced fatigue in turn to promote endurance performance in young athletes.
METHODS: Eight male athletes (aged 21.2±1.5 years; BMI. 23.3±1.8) participated in this single-blind crossover designed study and randomly instructed to either oral resveratrol supplementation (500 mg per day for 3 days) or placebo. The experimental morning, all subjects received resveratrol supplementation again at 60 minutes prior to a cycling exercise challenge at 80% VO2max with 60 rpm, and total cycling performance time were recorded. Simultaneously, blood samples were obtained to analyze the changes in blood glucose, plasma non-ester fatty acid, serum lactate dehydrogenase (LDH), creatine kinase (CK), uric acid (UA), total antioxidant capacity (TAC), malondialdehyde (MDA), reduced glutathione (GSH), oxidized glutathione (GSSG), tumor necrosis factor (TNF), and interleukin-6 (IL-6).
RESULTS: The exhausting time of 60 rpm cycling exercise challenge at 80 %VO2max were not significantly increased in RES comparing to that in placebo. Identically, the blood glucose and non-essential fatty acid did not significantly differ between two groups. The concentrations of the fatigue markers LDH, CK, and UA were similar results to those of energy metabolism biomarkers, no significant difference between RES and placebo. There were no significantly higher in RES comparing to placebo on antioxidant, oxidative stress and inflammation indicators during intensity cycling.
CONCLUSION: The results have shown that oral resveratrol supplementation couldn't blunt the response of oxidative stress, inflammation and attenuate subsequent exercise-induced fatigue, as well as fail to promote endurance performance. Therefore, we suggest that resveratrol cannot be served as ergogenic aid to alleviate the exercise-induced fatigue during high intensity cycling exercise.

COMPARATIVE STUDY ON DIETARY HABITS INFLUENCING DEGREE OF SATISFACTION WITH DIETING BETWEEN CHILDHOOD AND YOUNG ADULTHOOD

ANNOURA, T.1, SAKAGUCHI, H.1, SAKAGUCHI, S.2, AOYAGI, O.3

1. JAPAN UNIVERSITY OF ECONOMICS, 2. FUKUOKA SEISHU HOSPITAL, JAPAN, 3. FUKUOKA UNIVERSITY, JAPAN

INTRODUCTION:A variety of factors like with whom, what foods, how much, and when people eat impact the satisfaction with their dieting. In particular, it is feasible to think that there is a significant age gap between the influencing factors. Whereas there is no choice about how and what to eat foods in childhood, young adults can have their own dietary habits. In addition, it is also feasible that these influencing factors are interrelated. Thus, this study investigates dietary habits influencing degree of satisfaction with dieting in childhood and young adulthood by using Quantification Theory Type One (QTTO).
METHODS: A questionnaire survey concerning the degree of satisfaction with dieting in elementary school years and the present day using a 5-level scale from "very satisfied" to "not at all" was conducted with 322 Japanese female N-university students in September 2017. In addition, respondents were questioned about 13 dietary habits in elementary school years and the present day. Then, QTTO was conducted using the degree of satisfaction as a dependent variable and dietary habits as independent variables. The extent to which the dietary habits impacts the degree of satisfaction is examined using multiple correlation coefficients (MC), partial correlation coefficients (PC) and the range of category weights (RCW).
RESULTS: When comparing elementary school years and university years, MC in the latter was higher with 0.698 than the former was with 0.580. Also, whereas only 6 items of "What did you eat for breakfast?" "With whom did you eat dinner?" "What did you eat for dinner?" and others showed more than 0.2 of PC in elementary school years, high PCs more than 0.2 were found in 10 items except for "Where was the most seasoning used, at home or other dining locations?" "How frequently did you adjust the amount of food you ate?" and "How frequently did you go on a diet?"
CONCLUSION: This fact indicated that the satisfaction with dieting changed in university years more than in elementary ones. Whereas with whom to eat at dinner rather than at breakfast influenced satisfaction in elementary school years, in university years with whom to eat in breakfast impacted the satisfaction as well as at dinner. For breakfast they preferred to eat a simple meal such as a rice ball only. However, for dinner, it was found that satisfaction tended to improve by eating a meal consisting mainly of bread and when dining with many other people. Also, for the amount of food, satisfaction was improved by eating a lot of food. This seemed to be in opposition to the constantly reducing amount of food eaten when dieting.

EFFECT OF CARBOHYDRATE AND PROTEIN CO-INGESTION ON COGNITIVE FUNCTION OF SOCCER PLAYERS

SUN, F., TSE, C.F.

THE EDUCATION UNIVERSITY OF HONG KONG

INTRODUCTION:Soccer is notable for frequent intermittent high-intensity exercises and dependent upon various factors related to match play, including tactical, technical, physiological and psychological variables. Cognitive functions are important for soccer players, as they need to anticipate and react continuously to a changing and relatively unpredictable situation in the field. The purpose of the study was to investigate the effects of three solutions, i.e. carbohydrate-electrolyte-solution (CES), carbohydrate-electrolyte-protein-solution (CEPS), and placebo (PLA), consumption during soccer specific exercise protocol, i.e., Loughborough Intermittent Shuttle Test (LIST), on cognitive function of male college soccer players in Hong Kong.
METHODS: A total of 15 male college soccer player complete three main trials in a randomized cross-over study design. In each main trial, participants performed one LIST protocol, with the consumption of one of three solutions. The cognitive function test was conducted before and after LIST. Blood lactate, blood glucose, rate of perceived exertion, perceived of thirsty, abdominal discomfort and heart rate were also be measured at different time points during each trial.
RESULTS: Compared with PLA, the performances in the Rapid Visual Information Processing (RVIP) test, including reaction time and accuracy, were higher in the CES and CEPS trials. However, no differences were found between the latter two trials.
CONCLUSION: It seems that the consumption of CES and CEPS during soccer exercise may improve the cognitive function of male college soccer players, compared with PLA consumption.
The present study was supported by Internal Research Grant (RG 33/2017-2018R), The Education University of Hong Kong.

ASSOCIATION BETWEEN A SINGLE BOUT OF LOW- OR MODERATE-INTENSITY PHYSICAL ACTIVITY AND CHANGES IN TASTE THRESHOLDS

YOSHIDA, A.1,2, SUGII, S.2, TSUCHIDA, D.2

1: KYUSHU SANGYO UNIVERSITY, 2: TOYO UNIVERSITY

INTRODUCTION:Taste perception is an important factor not only for sustenance, but also for enjoying food and quality of life (Yoshinaka et al., 2016). Thus, taste perception is considered to be associated with health and well-being. Taste thresholds are influenced by various factors. There have been many studies on changes in taste after vigorous-intensity exercise. A clarification of the association between lower-intensity physical activity and taste may support the use of physical activity for health maintenance in daily life. This study aimed to determine whether taste thresholds changed after a single, brief bout of low- or moderate-intensity physical activity.
METHODS: Seven young adult males (21-22 years) participated in this study. The subjects performed three types of physical activities at different intensities (resting in a sitting position [1.0 METs], talking in person in a standing position [1.8 METs], and walking at 5.5 km/h [3.5 METs]) and did each physical activity for 30 minutes per week for 3 weeks (6-day washout). Differential thresholds for the five basic tastes (sweetness, sourness, saltiness, bitterness, and umami) were determined according to whole-mouth gustatory methods used in previous studies. The compounds used were taste solutions dissolved in bottled water. Samples were prepared for the assessment of sweetness (sucrose), sourness (citric acid), saltiness (sodium chloride), bitterness (caffeine), and umami (sodium glutamate hydrate) using five-level dilution techniques. The gustatory test was performed at two time points: before and after each physical activity. Participants height, body weight, and percentage of body fat were measured, and they were administered a questionnaire assessing their eating behaviours, dietary habits, and physical activity.
RESULTS: None of the participants had a taste perception disorder. Following low-intensity physical activity, a significant number of subjects improved their taste threshold for saltiness ($p<0.05$). With regard to umami, the taste threshold showed an improvement tendency. Moderate physical activity had potentially positive effects on the taste thresholds for bitterness and saltiness. All taste thresholds showed no change following the rest period. Changes in taste thresholds were not associated with subjects' lifestyles.

CONCLUSION: Gustatory thresholds can be improved through a single 30-minute bout of relatively low-intensity physical activity, but attributively. In the long run, these changes in taste perceptions influence eating behaviours such as food choices, and our results may contribute to good health. Further research with more subjects is needed on the correlations between taste perception, body mass, and continuous physical activity.

THE EFFECTS OF RICE INTAKE COMBINED WITH EXERCISE ON TOTAL GLUCAGON LIKE PEPTIDE-1 CONCENTRATIONS AND SUBJECTIVE FEELINGS OF HUNGER

SILALERTDETKUL, S.

SRINAKHARINWIROT UNIVERSITY

INTRODUCTION:Food intake is influenced by appetite hormone and appetite perceptions. It had been demonstrated that circulating glucagon like peptide-1 (GLP-1) was increased following white rice consumption. Interestingly, riceberry rice contains a lot of vitamin E, beta carotene, omega-3, and polyphenol. Therefore, the objective of this study was to investigate the effects of riceberry rice consumption compare with white rice consumption on total GLP-1 concentration relate to appetite perceptions.
METHODS: Twelve males age between 20 and 22 years participated in this study, which had been approved by the local ethics committee (body mass index, 23+ 3 kg/m2; percent body fat, 18+ 8 %; resting heart rate, 67+9 beat/min; systolic /diastolic blood pressure, 115± 12/71±8 mmHg; maximum oxygen consumption, 49 ± 5 ml/kg/min: mean ± SD). This experiment was a randomized crossover design with two main trials separately by at least 14 days. On one occasion participants consumed riceberry rice. On another occasion, participants consumed white rice. Additionally, participants were also asked to cycling for one hour at 80% maximum heart rate at 90 minutes following either riceberry rice or white rice consumption. Venous blood samples were taken at the baseline, 30, 60, 90, 150, and 180 min in both trials. Total GLP-1concentrations were measured by using the enzyme-linked immunosorbent assay. Subjective feelings of hunger was measured using visual analogue scale over a period of time. The data were analyzed using two way repeated measures ANOVA and paired t-test.
RESULTS: Two way repeated measure revealed no trial effect but there was a time effect as well as time and trial interaction of postprandial total GLP-1 concentration between two trials. Circulating total GLP-1 concentrations were increased significantly at 30 min and decreased significantly at 60 min following white rice and ricberry rice consumption ($p<0.05$). Additionally, postprandial total GLP-1 concentrations were significant increase at immediately and 30 min following exercise in both trials ($p<0.05$). Total GLP-1 concentrations in riceberry rice trial tended to be difference from white rice trial at 30 and 60 min ($p<0.05$). Subjective feelings of hunger was decreased significantly after consumed of riceberry rice and white rice. However, subjective feelings of hunger in riceberry rice trial was suppressed during and immediately after exercise ($p<0.05$).
CONCLUSION: There was no difference in postprandial total GLP-1 concentrations and subjective feelings of hunger between two trials. However, the increasing in postprandial total GLP-1 concentrations were induced by rice consumption and exercise. Interestingly, subjective feelings of hunger was altered by riceberry rice consumption. Future research will be needed to assess whether hunger hormone is affected by rice consumption.

ANALYSIS OF FACTUAL NUTRITION OF JUDOISTS

SUKHOV, S.

NATIONAL ANTI-DOPING CENTRE

INTRODUCTION:An analysis of factual nutritional status of athletes is a complicated endeavor since one has to take into account many variables and make a lot of calculations. Application of a proper software can considerably simplify and shorten the assessment of factual nutrition. A number of countries have developed software for assessment of nutritional status of athletes, but the set of food products and the list of courses are characterized with evident national features.
METHODS: We have developed software based on the nutrition requirements of athletes used in the Republic of Kazakhstan, which also takes into account the local patterns of nutrition. Along with other advantages, the software allows the analyzing of factual nutritional status of athletes. We have used the software for assessing the factual nutrition of 25 judoists. The athletes were catered at the same canteen. There was made an analysis of a seven-day master menu. After the instruction, the athletes kept food diaries recording all food products, courses and amounts consumed during each day of the week. We also conducted every day survey on any additional intake of food.
RESULTS: Factual food intake of athletes, at the caloric content of 4430 kcal, included 110 g of protein, with 45 g (40%) of animal protein, 110 g of fat (vegetable oil – 10 g/day), and 750 g of carbohydrates, including 200 g of added sugar. The recommended level of energy and nutrients for the given type of sports are 4600 kcal, 190 g of protein (including 60% of animal protein), 150 g of fat (including 1/3 in the form of vegetable oil), and 620 g of carbohydrates (including not more than 120 g of added sugar). There was noted the deficiency in the factual ration of meat products (100 g of meat, 20 g sausages and 30 g of poultry a day; while it is recommended to provide 260 g of meat, 65 g of sausages and 65 g of poultry a day), fruits (150 g/day; recommended 450 g/day), dairy products. The master menu did not provide fish. Amount of butter was twice above the recommended norm – 80 g/day. There was identified the deficiency of animal proteins, PUFA ω-6, PUFA ω-3, vitamins of group B, vitamins C, E, minerals, food fiber, and antioxidants. Actual ratio of required daily energy provided through protein, fat and carbohydrates was 10%-22%-68%, while the recommended ratio was 17%-29%-54%. Based on the findings, we have introduced appropriate modifications in the ration and master menu of judoists.
CONCLUSION: Analysis of factual nutrition with use of software allows expediting the identification of deviations from the recommended nutrition standards and timely correction of the ration and dietary pattern.

THE INFLUENCE OF EATING ATTITUDES ON DIETARY INTAKE OF FEMALE GYMNASTS IN SHANGHAI

XU, Q.

THE RESEARCH INSTITUTION OF SHANGHAI SPORTS SCIENCE

INTRODUCTION:Gymnastics including artistic gymnastics, rhythmic gymnastics and trampoline is a kind of aesthetic sports, whose athletes, especially female athletes have to had experienced the problems to achieve the ideal weight for a long time. In order to improve performance and meet the requirements of the aesthetics needed for the sports, such athletes have been always under the pressure to

reduce and control the weight, as diet is the important factor to influence weights. Female gymnasts have demands for energy intake in terms of physiology and psychology requirements to satisfy the periods of growth and development. But extreme dieting and other harmful eating behaviors may lead to the problems of anorexia athletica, female athlete triad, large range of weight change and even the risk of death. Compared with other athletes, more and more athletes competing in sports in which weight is considered important for performance are facing the problems of eating disorders. Learning about the eating attitudes and the condition of diet within three kinds of female gymnasts, and analyzing the relationship among them are helpful to do the work of nutrition intervention from another angle and improve their eating behaviors.
METHODS: Inbody 270 body composition analyzer, the eating attitudes test (EAT-26) and a simple food-frequency questionnaire were administered to collect the data of body composition, eating attitudes and the condition of eating of female gymnasts, including artistic gymnasts, rhythmic gymnasts and trampolinists. The differences and the relationship among them would be found by means of the statistical methods of one-way anova and correlation analysis.
RESULTS: 1. Oral Control had positive relation to the amount of energy, carbohydrate and protein intake per weight and the energy intake per fat free mass.
2. The female trampolinists were the worst in eating attitudes among the female gymnasts in the study.
3. The rhythmic gymnasts and the female trampolinists in the study did not have enough energy intake.
4. The amount of carbohydrate intake was ideal, but the percentage was low. The amount of protein intake was low, but the percentage was high. The percentage of the fat intake was high.
CONCLUSION: Eating attitudes have some influence on energy intake and dietary structure, among which oral control plays more important role.

EFFECT OF BETA ALANINE AND SODIUM BICARBONATE SUPPLEMENTATION ON INTERMITTENT SPRINT PERFORMANCE IN TEAM-SPORT PLAYERS

PHONGSRI, K., SENAKHAM, N., SENAKHAM, T.

DEPARTMENT OF SPORTS SCIENCE, FACULTY OF PHYSICAL EDUCATION, SRINAKHARINWIROT UNIVERSITY, THAILAND

INTRODUCTION:Nutritional strategies can be capable of increasing muscle-buffering capacity and attenuating the increase in acidosis during high-intensity intermittent exercise and might increase performance. Of interest is whether the combination of beta-alanine (BA) (intracellular muscle buffer via carnosine) and sodium bicarbonate (SB) (extracellular blood buffer) supplementation can lead to enhanced repeated-sprint performance beyond what is possible with either supplement alone (Ducker et al., 2013; Sale et al., 2011). This study examined the effects of beta-alanine with and without sodium bicarbonate supplementation on intermittent sprint performance in team-sport players.
METHODS: Fourteen well-trained male team-sport players supplemented for 28 d with beta-alanine (65 mg/kg body weight/day) or placebo. A cycling intermittent sprint protocols (CISP) consisted of twenty 2-min periods, each including 10 s of passive rest, 5 s of maximal sprint against a resistance of 7.5% body mass, and 105 s of active recovery was performed before supplementation (baseline) and twice after supplementation: after ingestion of sodium bicarbonate (0.3 g/kg body weight) and ingestion of a placebo using a randomized crossover procedure with 48 h between trials. Blood lactate, pH and bicarbonate concentration were measured before loading (post supplementation trials) and at pretest, 20 min following the pretest and posttest.
RESULTS: In the acute sodium bicarbonate loading trials led to increases in blood lactate, pH and bicarbonate concentration from before loading to pretest. Peak power output in CISP was increased in placebo + sodium bicarbonate and beta-alanine + sodium bicarbonate compared with baseline ($P < 0.05$). Beta-alanine + placebo did not significantly improve peak power output compared with baseline; however, beta-alanine + placebo was tended to increase the peak power output production slightly.
CONCLUSION: Results show that chronic beta-alanine supplementation did not significantly improve intermittent sprint performance in well-trained male team-sport players; however, there may be slightly positive effects on improvement in performance. Acute sodium bicarbonate supplementation significantly improved intermittent sprint performance. The addition of acute sodium bicarbonate to chronic beta-alanine supplementation may further enhance intermittent sprint performance.

EFFECTS OF ACUTE WEIGHT LOSS THROUGH WATER LOADING ON PHYSIOLOGICAL RESPONSES IN COLLEGE WRESTLERS

CHO, J.1, HAN, T.2

1. SUNGKYUNKWAN UNIVERSITY, 2. ANDONG NATIONAL UNIVERSITY

INTRODUCTION:Water loading, the consumption of large volume of water for several days prior to restriction, is one of the novel methods for acute weight loss in wrestler athletes (1). However, there is a lack of scientific investigation related to water loading on weight control. The purpose of this study was to investigate the effects of acute weight loss through water loading on the physiological responses in college wrestlers.
METHODS: Thirteen university male wrestlers participated and were randomly divided into control group (CON, n=6) and water loading (WLG, n=7). From 2-week to 1-week before weight-in, water loading was 30 and 100 ml/kg for CON and WLG groups, respectively. Before and after weight loss program body composition and blood pressure were measured. Blood was tested for hemoglobin (Hb), hematocrit (HCT), electrolyte, aldosterone and cortisol. Data were analyzed with two-way ANOVA with repeated measures on time using SPSS 18.0. $P<0.05$ was set as statistically significant.
RESULTS: Following acute weight loss program, body weight ($p=0.004$), BMI ($p<0.001$), muscle mass ($p<0.001$), body water ($p<0.004$) and systolic blood pressure ($p=0.046$) were significantly reduced and diastolic blood pressure ($p=0.043$) was significantly increased in the CON and WLG groups but there was no interaction between two groups. Blood HCT ($p=0.018$) and Cl- ($p=0.006$) were decreased and aldosterone ($p<0.001$) and cortisol ($p<0.001$) were elevated but there was no interaction between two groups.

CONCLUSION: This study suggested that assessment of water loading is safe and effective methods for acute weight loss in wrestler athletes.

VITAMIN D CONCENTRATION IN ICE HOCKEY PLAYERS OVER THE ANNUAL TRAINING CYCLE

OZIMEK, M., ORYSIAK, J., MALCZEWSKA-LENCZOWSKA, J., SITKOWSKI, D., SURALA, O., SZCZEPANSKA, B.

INSTITUTE OF SPORT-NATIONAL RESEARCH INSTITUTE

INTRODUCTION:Vitamin D deficiency is common in athletes, especially among disciplines training indoors[1]. In athletes, vitamin D status has been associated with sport performance [2] or resistance to infection [3].The aim of the study was to examine the fluctuations of serum vitamin D concentrations in ice hockey players over 1 year training cycle.
METHODS: Twenty seven male ice hockey players (17.0±0.5 years; body mass 77.2±7.8 kg; body fat 13.0± 3.0 %) participated in the study. Blood samples were collected three times (October'14, March'15 and October'15) to determine changes in serum 25-hydroxyvitamin D (25(OH)D) concentration over the annual training cycle.
RESULTS: The mean serum 25(OH)D concentration was 22.3±5.8 ng/ml (range: 12.5-35.4 ng/ml); 16.6±6.9 ng/ml (range: 6.0-33.3 ng/ml); 26.2±7.2 ng/ml (range: 13.0-40.7 ng/ml) in the first (post summer), second (post winter) and third (post summer) time point, respectively and differed significantly over time. The 25(OH)D concentration was significantly lower after a winter season than after a summer season (time point 1 and 3). Only 11% , 7% and 26% of the ice hockey players had 25(OH)D concentration above 30.0 ng/ml in the first, second and third time point, respectively. After a winter season, 18.5 % of participants had severe deficiency (<10 ng/ml) [4] of vitamin D.
CONCLUSION: Despite registered fluctuations of 25(OH)D concentration over annual training cycle, vitamin D insufficiency/deficiency was highly prevalent in ice hockey players, even after the period of the highest sun exposure.
The study was financially supported from the budget for science in years 2013-2015 by Ministry of Science and Higher Education in Poland (grant number: RSA2 006 52 and 102.05).

THE RELATIONSHIP BETWEEN NUTRIENT AND FOOD-GROUP INTAKES AMONG MALE JAPANESE HIGH SCHOOL SOCCER PLAYERS

CHINEN, S.1, MIYAHARA, K.2

1:OKINAWA UNIVERSITY, 2:NAGASAKI INTERNATIONAL UNIVERSITY

INTRODUCTION:It has been well-recognized that nutritional management is important for athletes to improve their performance, and this is also true for students who participate in sports as their school-based extracurricular activities.
In the present study, we conducted a dietary survey of high school soccer players in Nagasaki Prefecture to evaluate their dietary patterns and use them as a basis for future nutritional intervention.
METHODS: Twenty-four male members (age, 16 ± 1 years; height, 171.7 ± 5.3 cm; weight, 59.1 ± 6.5 kg) of a high school soccer club underwent 3-day weighed food recording (for 2 weekdays and 1 weekend day). Nutrient and food-group intakes were calculated using Excel Eiyo-kun software. Data were statistically analyzed using SPSS Statistics 22 software, and stepwise multiple regression analyses were performed to examine the effect of food-group intakes on nutrient intakes.
RESULTS: As the results, the food group that showed the highest regression coefficient for energy intake was meat (0.479), followed by grains (0.398). The most significant food-group contributors to the intake of each nutrient were as follows: protein, meat (0.619); fat, meat (0.766); carbohydrate, grains (0.753); calcium, milk (0.863); iron, meat (0.504); fiber, light-colored vegetables (0.491); retinol equivalent, meat (0.711); vitamin B1, light-colored vegetables (0.582); vitamin B2, milk (0.600); and vitamin C, fruits (0.573).
CONCLUSION: These results suggest that meat and grains are the dominant contributors to the intakes of energy and energy-yielding nutrients of male Japanese high school soccer players. Further analysis of the results and extrapolation of the present dietary intake data will provide a useful basis for designing nutrition education programs for youth sport participants.

EFFECTS OF SALVIA MILTIORRHIZA EXTRACT SUPPLEMENTATION ON PHYSIOLOGICAL AND PSYCHOLOGICAL RESPONSES DURING ACUTE HIGH INTENSITY INTERVAL EXERCISE IN FEMALE BASKETBALL PLAYERS

LEE, Y.

NATIONAL TAIWAN SPORT UNIVERSITY

INTRODUCTION:Basketball is considered an intermittent high-intensity sport. The physical fitness of basketball players can be influenced by both aerobic and anaerobic capacities (Montgomery et al., 2010). High intensity interval training can improve the aerobic and anaerobic ability of active males. The heart rate (HR) and blood lactate (LA) were increased during high intensity interval training (Engel et al., 2018). Danshen (Salvia miltiorrhiza) is a widely used Chinese herb for the treatment of coronary disease and reducing the heart rate (Lo et al., 1992). Therefore, the aim of this study was to examine the effects of SM extract supplementation on physiological responses during acute high intensity interval exercise (HIIE). We hypothesized that SM extract supplementation would improve the physiological and psychological responses during HIIE.
METHODS: Twenty-four female basketball players (aged 18-23 years) were recruited into the study. Subjects were divided into SME or placebo (PLA) groups according to their maximal oxygen uptake (VO2max), and then consumed 3 g of Salvia miltiorrhiza extract (equal to 12 g raw herbal of Salvia miltiorrhiza) or lactose per day for eight weeks. Subjects performed the HIIE tests with sixteen 2-min running bouts at the velocity of 90% VO2max separated by 2-min rest periods before (Pre) supplementation, at the 4th-week (Mid), and 8th-week (Post) after the supplementation. The heart rate, scores of rating of perceived exertion (RPE) were collected before HIIE and at the end of 4th, 8th, 12th, and 16th bouts of HIIE. And the scores of profile of mood states (POMS) in dimensions of fatigue and vigor were also collected before and after the HIIE.
RESULTS: The HR, and scores of RPE significantly increased after HIIE in both SME and PLA groups at Pre, Mid, and Post of the supplementation. Moreover, the fatigue score on the POMS significantly increased, and the score of vigor significantly decreased after HIIE in both groups as well as at Pre, Mid, and Post of the supplementation. However, there were no significant differences between SME and PLA groups or among the supplementation time periods.

CONCLUSION: The results of HR, as well as score of RPE, and POMS couldn't support the hypothesis of this study. Therefore, daily consuming 3 g of Salvia miltiorrhiza extract for 4 or 8 weeks don't benefits on the physiological and psychological responses during HIIE.

CYSTINE SUPPLEMENTATION IMPROVES EXERCISE PERFORMANCE BY INCREASING MUSCLE GLYCOGEN AND MITOCHONDRIAL ACTIVITY

KATO, H., MIZUGAKI, A., NOGUSA, Y., HASEGAWA, T., INOUE, Y.

AJINOMOTO CO., INC.

INTRODUCTION:Exercise-induced inflammation has a negative impact on exercise performance and gut barrier function (1). Bovine colostrum supplementation, which suppresses inflammation and exercise-induced disruption of gut barrier (2), improved exercise performance (3). We previously found that cystine (Cys2) or glutamine (Gln) suppressed exercise-induced disruption of gut barrier through suppressing systemic inflammation. However, it remains to be clear if Cys2 or Gln improve exercise performance. Therefore, we evaluated the effects of Cys2 and Gln on exercise performance.
METHODS: Experiment1 (Ex1): Male CD2F1 mice were fed AIN93G control diet or control diet supplemented with 2 % amino acids (Cys2 or Gln) for 10 days. After 7 days of feeding, the mice ran on a treadmill until exhaustion once a day for consecutive 3 days. Food intake and time to exhaustion were measured on each day.
Experiment2 (Ex2): Male CD2F1 mice were fed with control diet or control diet with 2 % Cys2 for 7 or 10 days. CD2F1 mice ran on a treadmill until exhaustion once a day for 2 consecutive days following 7 days of feeding. Time to exhaustion were measured on each day. Gastrocnemius muscle were collected the day after 7 days of feeding (i. e. before 1st exercise) or the day after 2nd exercise. Glycogen content, gene expression related with glucose and fat metabolism and mitochondrial biogenesis were analyzed in the skeletal muscle.
RESULTS: Ex1: Cys2 or Gln supplementation significantly increased food intake after 3 bouts of exercise, compared to control diet. While Gln supplementation had no effect on the time to exhaustion and muscle glycogen content, Cys2 supplementation significantly prolonged the time to exhaustion at 2nd and 3rd exercise.
Ex2: Mitochondrial biogenesis marker and citrate synthase activity were significantly increased by 7 day feeding of Cys2-contained diet. Together, Cys2 supplementation reduced free fatty acid concentration in plasma and increased gene expression of fatty acid binding protein on muscle. Glycogen content, and gene expression of glucose transporter 4 and glycogen synthase in Cys2 group were significantly higher than in control group in the day after 2 bouts of exercise.
CONCLUSION: Supplementation of Gln or Cys2 significantly alleviated the exercise-induced decrease in food intake. Moreover, Cys2 increased exercise performance, possibly due to increase in muscle glycogen content, mitochondrial capacity and fat utilization.

RELATIONSHIP BETWEEN WEIGHT CHANGES AMONG RETIRED MALE JUDO PLAYERS AND THEIR WEIGHT CLASS AND RANGE OF WEIGHT LOSS AT THE TIME OF COMPETITION

ITAKA, T., UNO, M., INOUE, K., TSUKADA, M., AGEMIZU, K.

TOKAI UNIVERSITY

INTRODUCTION:The weight of players after they retire from competition is extremely important in terms of their health. Cardiometabolic risks are known to be especially high among retired heavyweight class players. Although studies on American football players have been conducted, no studies have yet been conducted on weight among retired Japanese judo players. There is anecdotal evidence that weight gain among retired players who underwent significant weight loss for a class division competition is greater than in those who underwent minimal weight loss. However, this has not yet been scientifically proven.
Therefore, the present study was conducted to determine if weight changes among retired judo players were related to their weight class and range of weight loss at the time of competition.
METHODS: The participants were 58 male graduates from the Men's Judo Club of T University, where they competed in judo. Questionnaires were sent to the participants, and they included questions regarding the judo weight class in which they had competed, presence or absence of weight loss requirement, range of weight loss, current weight and body fat percentage. Questions regarding frequency of playing judo or performing exercises other than judo and those regarding their current lifestyle, such as food intake changes after retirement, were also included. Responses collected from 37 participants were analysed. The average, minimum and maximum values of current weight were classified based on the questionnaire responses and analysed.
RESULTS: The average age of the participants was 25.6 years (range, 22–33 years). For the participants who were in the 60 kg weight class (n = 4) when they were active players, the average current weight was 75.5 kg, whereas for those who were in the 100 kg weight class, it was 105.4 kg. The ranges of weight loss were divided into 4 groups: 1–3 kg, 3–6 kg, >6 kg and no weight loss, to analyse weight gain after retirement. Participants in the 1–3 kg weight loss group gained a maximum of 7 kg more than the weight at each class, whereas one participant in the >6 kg weight loss group gained more than 20 kg. Moreover, there was a correlation between food intake and weight gain after retirement when food intake changes were analysed.
CONCLUSION: Various factors influence weight changes among retired male judo players. The findings indicate that weight changes in players after retirement are impacted by their weight class and range of weight loss at the time of competition.

COMPARISON OF GC-MS AND MEKC METHODS FOR CAFFEINE DETERMINATION IN PRE-WORKOUT SUPPLEMENTS

WARAKSA, E., POKRYWKA, A., KONOP, M., NAMIESNIK, J., OZIMEK, M., KLODZINSKA, E.

INSTITUTE OF SPORT - NATIONAL RESEARCH INSTITUTE

INTRODUCTION:The caffeine (CAF) belongs to the group of xanthine alkaloids derived from seeds, leaves, and fruits of certain plants. For many years, CAF was included in the List of Prohibited Substances and Methods in Sport but since 2004 it has been no longer restricted. Nevertheless, the monitoring program has been applied to determine a possible increase in CAF consumption. The stimulating impact of

CAF on the central nervous system and widespread occurrence in a variety of plants have contributed to the high popularity of CAF containing products. To determine the optimal dose of CAF and other supplement ingredients, a reliable information about their content on the label of products is significant. Unfortunately, since the last decade of the 20th century, the sports community has been struggling with the problem of unreliable products from the market of dietary and/or nutritional supplements. Therefore, the quantitative and qualitative compliance of the declared composition with the real one is of great importance.
METHODS: In this study, GC-MS- and MEKC-based methods for determination of caffeine in pre-workout supplements were developed and validated. The proposed protocols utilized minimal sample preparation (simple dilution and syringe filtration).
RESULTS: The developed methods achieved satisfactory validation parameters, i.e. good linearity (R2>0.9988 and R2>0.9985 for GC-MS- and MEKC-based method, respectively), satisfactory intra- and inter-accuracy (within 92.6 – 100.7% for method utilizing GC-MS and 92.1 – 110.3% for protocol based on MEKC) and precision (CV<15.9% and CV<6.3% for GC-MS- and MEKC-based method, respectively) and recovery (within 100.1 – 100.8% for method utilizing GC-MS and 101.5 – 106.2% for protocol based on MEKC). The limit of detection was 0.03 and 3 µg/mL for method utilizing GC-MS and MEKC, respectively. The CAF concentrations determined in investigated pre-workout supplement samples by GC-MS- and MEKC-based methods were found to be in the range of 8.53 – 11.23 and 8.20 – 11.61 µg/mL, respectively.
CONCLUSION: The results obtained in this study confirmed the literature reports on incompatibility of the declared supplement compositions with the real ones (the CAF concentrations were within 110.0 – 167.3% of these declared on the product labels). However, the consumption of investigated supplements in accordance with label instructions would not result in exceeding the safe CAF level of 400 mg per day.

QUANTITATIVE ASSESSMENTS OF 3-D HUMAN BODY SHAPE IN JAPANESE SEDENTARY WOMEN BY USING HOMOLOGOUS BODY MODEL - THICKNESS DISTRIBUTION PATTERN IN OBESE FIGURES -

SOMA, M.1,3, IKEGAWA, S.1, FURUTA, N.1, KASHIWAGI, Y.2, FUNATO, K.3

1: JUMONJI UNIVERSITY , 2: SENSHU UNIVERSITY , 3: NIPPON SPORT SCIENCE UNIVERSITY

INTRODUCTION:Overweight and obesity are great concerns throughout the life-course in sedentary peoples.As for the assessment of obesity conventional methods such as the Martin-type or Tape measures have been used for human body anthropometry such as length and circumference of each body segment. There is a few studies for quantifing the segment shape for identifying the characteristicsed body shape in obese figures. Constructing the homologous human body model and analysing it by principal component statistical analysis are useful for describing and assessing the specific features of 3-D shape. i.e. foot shape analysis by using principal component analysis [1]. The purpose of this study was to compare the morphological body shape characteristics between Japanese females by quantifying 3-D body shape established by a Principal Component Analysis (PCA) of Homologous Body Model (HBM).
METHODS: The body shape of 41 underweight (BMI＜18.5), normal weight (18.5≦BMI＜25.0) and over weight (25.0≦BMI＜30) age (20.5±0.5 years) females was quantified using a 3D scanner. 3-D whole body line scanner (BLS; Hamamatsu Photonics Ltd, Japan) was used to scan their standing whole bodies put on the skin. HBM had constructed by fitting the whole body laser scan called polygon date to generic template model based on anatomical landmarks. HBM consisted of 20,000 vertex of the same topology, and each data point was calculated based on the anatomical landmarks. Subcutaneous fat thickness measurements were made on the biceps femoris, iliac crest, brachioradialis, triceps, subscapular, medial calf, front thigh, supraspinale and abdominal, Biceps the upper and lower extremities with using B-mode ultrasonic device employing a 5 MHz transducer.
RESULTS: The 11 PCs had explained 90.3% of the shape variability, respectively. In particular, PC1 (contribution ratio; 51.2%) explained total body volume and thickness and PC2 (contribution ratio; 11.1%) trunk ratio and thickness. In normalized HBM as to body height, the total body volume, small trunk ratio, larger and thicker in chest, upper arm, abdominal and biceps femoris were characterized as overweight. Homology model of the 3-D body shape enabled to quantify the individual differences and characteristics of body shape. One of the advantages of Principal Component Analysis statistical shape analysis was that it provided intuitive visualization of the shape variation. The shape analysis results revealed the differences that cannot be detected from 1-D and 2-D measurements.
CONCLUSION: 3-D human body shape using by homologous body model in over weight body shape was characterized a total body volume, small trunk ratio and thicker subcutaneous in chest, upper arm, abdominal and biceps femoris were characterized. Over weight and obese figures in Japanese sedentry women were quantified by 3-D human body shape. Homologous body model is useful for assessments of the body shape from the viewpoints of life stage, growth, development and training.

DIETARY MISTAKES OF POLISH ATHLETES IN RELATIONSHIP TO THE FREQUENCY OF CONSUMPTION OF FOODS RECOMMENDED IN THE SWISS FOOD PYRAMID FOR ACTIVE PEOPLE

FRACZEK, B., GACEK, M., PIETA, A., TYRALA, F., MAZUR-KURACH, P.

UNIVERSITY OF PHYSICAL EDUCATION IN KRAKOW, POLAND, DEPARTMENT OF SPORTS MEDICINE AND HUMAN NUTRITION

INTRODUCTION:Necessity of monitoring dietary habits in individuals characterized by higher physical activity levels constituted a rationale for this study, aimed at assessing the nutritional habits among Polish athletes in the context of the Swiss food pyramid guidelines.
METHODS: Research was taken among 610 professional athletes (219 women and 391men) of the age of 18-30 years (mean 22,05±3,08), practicing various sport disciplines. All participants completed an original questionnaire examining their dietary habits and frequency of consumption of food products recommended for active people. Distribution of dietary behaviors in relation to gender, the character of the sports (team vs. individual) and the level of sports (master class vs. others) were compared using the chi2 test.
RESULTS: It has been shown improper frequency of consumption of oils (61.78%), cereal products of high grist (59,90), vegetables (53,62%), dairy products (52,09%) and fish (40,36%). Statistical analysis showed that significantly fewer men than women eat raw vegetables every day ($p < 0.01$) and whole grain cereals ($p < 0.05$), less frequently confine fats, sweetened carbonated, energetic beverages and Fast food products ($p < 0.01$). Women, in turn, rarely consume meals and fish with sufficient regularity ($p < 0.01$) and proper complement fluids during training ($p < 0.05$).
CONCLUSION: The limited scale of implementation of the nutritional recommendations for athletes confirmed the validity of the monitoring and targeted rationalization of diet, taking into account the diverse nutritional problems, depending primarily on gender and sports level.

THE EFFECTS OF 10-WEEK LEUCINE SUPPLEMENTATION ON MUSCLE GROWTH, BODY COMPOSITION, METABOLISM, INFLAMMATION AND WELLBEING OF ADOLESCENTS AND YOUNG ADULTS WITH CEREBRAL PALSY

THEIS, N.1, BROWN, M.A.1, WOOD, P.2, WALDRON, M.3,4

<1> UNIVERSITY OF GLOUCESTERSHIRE, <2> TRELOAR'S SCHOOL AND COLLEGE, <3> ST MARY'S UNIVERSITY, <4> UNIVERSITY OF NEW ENGLAND

INTRODUCTION:Cerebral palsy (CP) is caused by damage to the developing brain, leading to altered patterns of growth and development (1). This causes muscle weakness and over time, a progressive loss of muscle mass, which compromises daily motor function. This muscle atrophy may be attributed, in part, to a blunted muscle protein synthetic response and the presence of chronic low-grade inflammation. Leucine supplementation has been reported to stimulate muscle protein synthesis (2) and reduce inflammation (3), and could therefore be a promising intervention to increase muscle mass or prevent muscle atrophy for those with CP. This study aimed to assess the efficacy of 10-week leucine supplementation on muscle mass, strength, inflammation, body composition, metabolism and subjective wellbeing in adolescents and young adults with CP.
METHODS: Twenty-two participants were randomly assigned to a control group (n = 11) or a leucine group (n = 11), where leucine (192 mg/kg body mass) was administered every day for 10 weeks. Elbow flexor muscle strength (measured by maximal voluntary contraction using hand-held dynamometry) and muscle volume (measured by 3D ultrasound technique), systemic inflammation (C-reactive protein (CRP) concentration), body composition (measured by CP-specific skinfold assessment), metabolic rate (measured by indirect calorimetry) and wellbeing (self-reported questionnaire) were assessed before and after the intervention period.
RESULTS: There was a significant increase in muscle strength ($p = 0.027$), muscle volume ($p = 0.001$) and perceptions of wellbeing ($p = 0.006$), and a significant decrease in CRP ($p = 0.045$) in the leucine group compared to the control group following 10 weeks of leucine supplementation. This equated to a 26% increase in muscle strength and a 3% increase in muscle volume, accompanied by a 60% reduction in inflammation in the leucine group. No changes in metabolic rate or body composition were observed in either group.
CONCLUSION: Ten-week leucine supplementation improved muscle strength and muscle volume, which could be partly explained by a concomitant reduction in systemic inflammation in those with CP. Therefore, leucine supplementation might be an appropriate strategy to prevent muscle atrophy, particularly in those with more severe CP who are unable to take part in traditional exercise. The improved wellbeing of the leucine-fed CP group also highlights its alternative roles and capacity to improve the quality of daily living.

ASSOCIATIONS BETWEEN DISORDERED EATING AND LABORATORY-BASED HEALTH PARAMETERS IN ADOLESCENT ELITE ATHLETES AND CONTROLS

WESTERN, B., STENQVIST, T.B., TORSTVEIT, M.K.

UNIVERSITY OF AGDER

INTRODUCTION:Athletes seem be more vulnerable to disordered eating (DE) than the general population, however there is inconsistency in the literature whether this applies to adolescent athletes. DE have been linked to performance- and health consequences such as reduced energy intake, low fat percentage (fat%), low resting metabolic rate (RMR), and reduced bone mineral density (BMD) among adult athletes, less is known in adolescent samples. The aims of this study were therefore to investigate the prevalence of DE, as well as possible associations between the degree of DE and RMR, body composition, spine BMD and nutritional factors in adolescent elite athletes and non-athletic controls.
METHODS: A total of 36 male and female high school elite athletes competing in endurance- and ball-game sports, and 16 controls attending a general high school study program, were included in this cross-sectional study (age (mean ±standard deviation): 16.4 ±0.3 years). Subjects were classified with DE if they scored above cut-off on the Eating Disorder Examination Questionnaire (EDE-Q) (Global score >2.6), furthermore, all four subscales of the EDE-Q were included. Body composition and BMD were measured using Dual-energy X-ray Absorptiometry (DXA), and RMR was assessed using indirect calorimetry with an open hood canopy system. All tests were performed in a fasted state and followed standardized best practice protocols. Mean intake of daily calorie per kg fat free mass (FFM), and gram protein, carbohydrate and fat per kg FFM, were calculated from a three-day dietary recall interview. Correlations were found using Spearmans rho.
RESULTS: Median for Global score was 0.05 and 1.45 (25-75 percentile: 0.00-0.52 and 0.50-2.32) for athletes and controls, respectively ($p<0.01$). Significant differences in all EDE-Q subscales were also found comparing athletes and controls ($p<0.01$). No athletes, but three controls were classified with DE. There were no significant correlations (COR) between DE and RMR. In controls there was a positive COR between Restraint and BMD (0.530, $p<0.05$). In the total sample, fat% COR positively with both Global score (0.413, $p<0.01$), Restraint (0.517, $p<0.01$), Eating concern (0.345, $p<0.05$), Shape concern (0.469, $p<0.01$) and Weight concern (0.418, $p<0.01$). In controls, fat% COR positively with Shape concern (0.658, $p<0.01$) and Weight concern (0.519, $p<0.01$), while in athletes, BMI and fat% showed a lower positive COR with Restraint (0.396, <0.05 and 0.345, $p<0.05$ respectively). There were no COR between DE and mean kcal per kg/FFM, or gram protein, carbohydrate and fat per kg/FFM in either athletes nor controls.
CONCLUSION: We found a low prevalence of DE and few associations between DE and laboratory based health parameters, except for body composition. Higher DE scores COR positively with BMI and fat% in both athletes and controls, indicating that a more unfavorable body composition is associated with a higher degree of DE behavior.

Philosophy and Ethics

PE PROJECT. MEASURING IMPACT AND EFFECTIVENESS

HESZTERÁNÉ, E.J.

EÖTVÖS LORÁND UNIVERSITY

Introduction
The aim of Physical Education is to develop students physical competence and knowledge and their ability to use these to perform in a wide range of activities associated with the development of an active and healthy lifestyle in their entire life. In addition to this, Quality

Physical Education might be of crucial importance in the development of 21st century skills like creativity, critical thinking, collaboration, cooperation and communication. We firmly believe that a PE project is an effective method to achieve our aims.
Methods
Thirty teachers participated in the research, using the project approach in activities related to competence development and leisure sport in 30 classes. Adequate to the method the content of the project was negotiated by the learners and the PE teacher and they also shared the tasks and the responsibilities during the project. Besides the PE lessons they organized out-of-school programmes and used the project method in other classes for example in physics and in biology. The efficiency of the project was measured by a pre-test and a post-test. We also used psychomotor ability tests and the perceived motivational climate in PE with the help of a PMCSQ-2 questionnaire. The data have been processed by the Paired Samples test.
Results
In the field of psycomotor skills 85% of the learners performed significantly better at the post-test (p 0,02) than at the pre-test. Their development in acquiring the material equals with that of using other methods. The PMCSQ-2 analysis suggested that the Task-Involving climate increased and the Ego-Involving climate decreased during the PE project. The Cooperative Learning, the Effort/ Improvement and the Important Role subscales of Task-Involving climate increased significantly (p 0,00; 0,00; 0,00). The rate of Intra-Team Member Rivalry and Unequal Recognition was significantly less (p 0,01; 0,002). Only the Punishment for Mistakes subscale of Ego-Involving climate remained unchanged (p 0,691).
Discussion
The objective of the PE project is the transfer of knowledge and motivating formation of attitude by laying emphasis on physical literacy. For this reason the project connects the PE study material with certain topics and other subjects, also taking into consideration the outside world of the school. The project made possible for students the choice of different learning paths that reinforced their sense of competence (Braithwaite et al, 2011), increased their endeavors for advancement. The PE project is of equal efficiency with other methods in transferring study material, however, in the formation of attitude is of way more efficient than other traditional educational strategies.

PHYSICAL FITNESS IN PRE-ADOLESCENT STUDENTS FROM NORTHERN ITALY. THE "RAGAZZI A BRESCIA" PROJECT

PERINI, R., CUDICIO, A., COGLIATI, M., ORIZIO, C.

UNIVERSITÀ DI BRESCIA

INTRODUCTION:A growing number of children does not meet the physical activity (PA) recommendations. Moreover, PA levels significantly decrease with age in schoolchildren, occurring the greatest decline in pre-adolescence. Early interventions are thus crucial to prevent sedentary habits and negative influences on health. With the final aim of incrementing PA practice, the "Ragazzi a Brescia" project was designed to collect data related to physical fitness as basis for appropriate administration of physical education in middle-lower school.
METHODS: 331 eleven-year-old students were evaluated, 168 males (M) and 163 females (F). We measured: a) height (m) and body mass (kg), then calculating BMI; b) the distance (m) covered during the "six minutes walking test" (6MWT); c) the length jumped (cm) in "standing broad jump test" (SBJT); c) the distance (cm) attained in "V-Sit and Reach test" (V-SRT).
RESULTS: BMI was 20.0±3.4 and 19.7±4.1 in M and F, respectively (p>0.05). The distance covered in 6MWT showed a tendency to be greater in M than in F, being 712±70 m and 690±53 m, respectively. In SBJT, M jumped significantly more than F, i.e. 150±23 cm vs 141±21 cm. In contrast, better performance was obtained in V-SRT by F, who reached 3±10 cm compared to -6±7 cm obtained by M.
CONCLUSION: The mean value of BMI of both genders is close to the 50th percentile reported for 11-year-old boys and girls of North Italy. Nonetheless, a not negligible number of students (about 15% of M and 11% of F) have to be considered overweight (1). The performances in 6MWT and SBJT were on the average even better than those reported for age-matched European adolescents (2-3), suggesting a good level of both cardiorespiratory and lower-limb muscular fitness. As expected, results in V-SRT were strongly influenced by gender, as only F showed a good low-back flexibility.
As a whole the observed data would indicate a satisfying level of physical fitness in these pre-adolescent students. Thus, they can be considered able of properly following a physical education curriculum, that should take into account some gender-related differences. The aim of increasing physical activity in daily life and discouraging its abandon during adolescence could be hopefully reached.

EXAMINATION OF THE INFLUENCE OF SHORT-TERM NATURE EXPERIENCE ON SPIRITUAL PAIN.

KIJI, M., KASE, T., NIGORIKAWA, T.

RIKKYO UNIVERSITY

Introduction
Many studies have shown that human's health and spirituality have close relations. In addition, several studies mentioned that staying in the natural field could enhance one's sense of spirituality. On the other hand, spiritual pain is considered to be a type of mental distress associated with lack of spirituality. This study tried to examine the potential of short-term nature experience to reduce spiritual pain.
Methods
The subjects of the study consisted of 20 male and 23 female university students (mean age = 19.5). The tendencies toward spirituality and spiritual pain were measured using the Survey for Nature and Outdoor Experience 2 (SNE2), the Japanese Youth Spirituality Rating Scale (JYS), the Purpose In Life Test (PIL) and the General Health Questioner 12 (GHQ12). Using these scales, a correlation analysis and the corresponding t-test were performed.
Results

In regard to the correlation analysis, the total score of spiritual pain and JYS, PIL were negatively correlated. In other words, those who had a high spiritual pain showed low spirituality tendencies suggesting the possibility of purpose in life is low. Moreover, the total score of spiritual pain was in positive correlation with the GHQ12. Namely , those with high spiritual pain showed data suggesting the possibility of low mental health. In addition, in the corresponding t-test the total score of spiritual pain decreased significantly after the short-term nature experience. Finally, the collapse of the value system and the absence of love and acceptance, which are subordinate concepts of spiritual pain, declined significantly after the short-term nature experience.
Discussion
Our previous study suggested that nature activities could enhance one's tendency of spirituality. This study aimed to investigate the impact of short-term nature experience on people with spiritual pain. As a result, data suggesting that short-term nature experience could reduce human spiritual pain was obtained. Since this study could not prepare and test a control group, further investigation is required to clarify this relationship.

ACTION PLANS OF PHYSICAL EDUCATION AS A SUBJECT FOR ENHANCING CORE COMPETENCIES

PARK, J.
INCHEON NATIONAL UNIVERSITY

Introduction
The 2015 core competency-based revised curriculum has been developed through a research and development process. Schools and teachers need to focus on teaching·learning methods and education assessment for the 2015 core competency-based revised curriculum to be applied successfully. Based on these necessities, this study presents action plans for enhancing the core competencies of Physical Education in the following three aspects: curriculum reorganization, teaching·learning, and assessment.
Methods
First, the present study, based on the national education development system and ideal role of teachers in gyms, proposes curriculum implementation as the educational process where teachers reconstruct the curriculum to develop lesson plans, and select and develop appropriate teaching·learning and evaluation tools in accordance to locations, schools, classes levels, and students. To identify ways of improving subject competencies, the national and international physical education curricula were analyzed. An on-site awareness of competences and a request for the 2015 revised national physical education curriculum were investigated. Competency-based classes were observed and teachers were interviewed on their implementation plans for the core competency curriculum.
Results and discussion
Based on this information, the present study proposes suggestions for improving competencies in physical education from the perspectives of revising the physical education curriculum, teaching·learning methods, and evaluation. For a revision of the physical education curriculum, it is necessary to analyze the 2015 revised national curriculum, in order to develop systematically the curriculum according to the level of schools and teachers, and to organize the concepts and sub-elements of physical education competencies. Furthermore, it is necessary to select and organize teaching contents that are pertinent to physical education competencies. In teaching, rather than focusing on a one-directional teaching method or subjective individual teaching methods, using teaching methods where teachers and students interact simultaneously would enhance core competencies, including after-school sports activities and community sports activities. The level and scope of the evaluation, development of the evaluation direction, and evaluation instruments and criteria should be established based on an achievement level. An analysis of support systems reveals teaching manual, expand 'inquiry-based teacher training', utilize 'on and off-line teachers' teaching communities', and establish a mentoring system.

THE CROSS-VALIDATION OF THE CANADIAN ASSESSMENT OF PHYSICAL LITERACY-II IN THE CHILDREN OF CHINA

LI, M.H., SUM, K., WAI, R.
THE CHINESE UNIVERSITY OF HONG KONG

The concept of physical literacy (PL) has received increasing attention during the last decade. How to accurately assess an individual's PL level has become a prevailing topic for many researchers. One of the most widely used PL assessment methods is the Canadian Assessment of Physical Literacy, 2nd version (CAPL-2), which is the first comprehensive protocol that can accurately and reliably assess a broad spectrum of skills and abilities that contribute to and characterize the PL level of a participating child. The purpose of this study was to cross-validate the CAPL-2 in Chinese children aged 8-12 years old.
A Chinese version of CAPL-2 (CAPL-2-CN) was finally confirmed through a back-reverse independent translation. A total of 323 children in South China were approached using a convenient sampling. Each domain of CAPL-2-CN has different assessment methods: Daily Behavior was objectively measured by ActiGraph GT3X+ accelerometer worn on the waist for children for seven consecutive days, and subjectively assessed by questionnaires; Physical Competence was assessed using PACER, Plank, and CAMSA; Knowledge and Understanding, and Motivation and Confidence were both subjectively measured using translated questionnaires of CAPL-2-CN.
In the first phase of data analysis, descriptive statistics was calculated using SPSS 22. Independent t-test was conducted to examine that there were significant differences in the total scores of PL among boys and girls ($p<.05$). Then the confirmatory factor analysis (CFA) was performed on data collected from 279 children (136 boys) who had completed raw scores for all CAPL-2 protocols. Although the results indicated a five-factor validity of CAPL-2-CN, which was different from the original four-factor CAPL-2, CFA proved that the construct demonstrated a good fit to the new model, containing five domains: Daily Behavior, Physical Competence, Knowledge and Understanding, Motivation and Confidence (I), and Motivation and Confidence (II).
It is concluded that the CAPL-2-CN showed a reliable and valid result as a measure of the PL level of the children aged 8-12 in China. More appropriate intervention programs should be recommended to younger generations by the physical education professionals in China with the progress of the cross-validation of CAPL-2-CN.

SPORTS ACTIVITY AS A FACILITATING FACTOR FOR COMMUNICATION SKILLS ACQUISITION BY UNIVERSITY STUDENTS

NOZAKI, M.1, ISOGAI, H.2, TAKAHASHI, M.1

1: NIHON UNIVERSITY 2:KYUSHU SANGYO UNIVERSITY

Introduction
Surveys using Kikuchi's Scale of Social Skills: 18 items (KiSS-18), the Bidimensional Resilience Scale (BRS), and a questionnaire on the environment of sports activities were performed in our previous study. The factor structure of the Kiss-18 was then checked and its scale was reconstructed. In Study 1, the reconstructed three-factor structure (communication skills, task coping skills, and skills of coping with interpersonal relationships) was used to examine how university students acquired the social skills. In Study 2, facilitation factors caused by sports activities were examined.
Methods
Subjects were grouped into Groups A (496 men and 201 women belonging to an athletic club in the university), B (458 men and 258 women belonging to a sports circle/club in/outside the campus), and C (1213 men and 745 women belonging to no sports activity group).
Study 1: a two-way ANOVA with the factors of sports activity and gender was performed.
Study 2: multiple regression analyses were performed to examine how environmental factors (the satisfaction level, atmosphere, and attractiveness of the team they belong to) and a psychological factor (resilience) affected the communication skills in Group AB, the combination of Groups A and B.
Results and Discussion
Study 1: no significant difference was found among the three groups nor between the genders regarding the total scores of the social skills. Regarding the communication skills, Groups A and B scored significantly higher than Group C, and women scored significantly higher. Regarding the skills of coping with interpersonal relationships, no significant difference was found among the three groups, but men scored significantly higher. Therefore, social skills altogether were equally acquired regardless of the sports activities or gender, but sub-skills were not. It was suggested that women were superior in the communication skills, and men the skills of coping with interpersonal relationships. Furthermore, the fact that Groups A and B had better communication skills surmised that the sports activities were important for triggering some facilitation factor to enhance their communication skills.
Study 2: Taking over the above results, facilitation factors were then examined, but no environmental factors influenced the communication skills. As for the psychological factors, significant regression equations were yielded in men and women in both Groups AB and C. The contribution ratios were over 50% each. It was thus verified that sociability of resilience impacted the communication skills. However, the sports activities could not be the only factor of facilitating the resilience, suggesting the need for a further study. In addition, this study assumed that some facilitation factors were the key to the communication skills improvement, but the sports activity itself might be the facilitation factor.

GYMNASTICS TO THE INFANT EDUCATION

RIBEIRO DA SILVA, A., EMANOELLA SILVA MARTINS DE SOUZA, E., LEÔNIDAS SOARES, J., FRUHAUF ULSENHEIMER, W., LURDES CENCI TSUKUDA, V., DE FRANÇA BARROS, J.

UNIVERSIDADE DE BRASÍLIA

INTRODUCTION:The inclusion of children in early childhood education is the first stage of transition from the domestic environment to the educational spaces, in which it will bring change and repercussions on their lives. At this stage the child is at the moment of the "sensitive experience", in which prevail the sensory references in its relationship with knowledge. The objective is to identify the contributions of gymnastics in the process of emancipation of the child, as it is expressed in games in the imaginary playground, as well as its importance to the process of learning and development.
METHODS: The methodology of the project is of an interpretative approach and qualitative focus, where it began with the review of the theoretical framework that guided the process in search of understanding of what we characterize here as "the world of children", seeking to reveal what children like, want and need. Addressing the importance of physical education teacher and educators who deal with the infant education in general, this process and its importance in the schoolchildren spaces.
There were performed 11 (eleven) interventions proposing sung jokes linked to the exercises, following a pre-established schedule and plan of action.
RESULTS: It was observed that some children were interested with the activity for a short time interval, quickly they scattered, generating a great difficulty in the beginning of the action, requiring a reflection on the future actions and activities. Subsequently, there was used the strategy of sung jokes and the use of music, so that the children would be interested in and involved with more time, it attaches to the fact that they are also responsible for the construction of the educational process. The song brought the children a more development, stimulating the motor coordination in a general way, making children more timid that used to not participate in the activities performed outdoors to participate with more enthusiasm, more loose, and wanting every day new games, with the realization of the project, the group of children become - if more kingdom.
CONCLUSION: It was observed that some children were interested with the activity for a short time interval, quickly they scattered, generating a great difficulty in the beginning of the action, requiring a reflection on the future actions and activities. Subsequently, there was used the strategy of sung jokes and the use of music, so that the children would be interested in and involved with more time, it attaches to the fact that they are also responsible for the construction of the educational process. The song brought the children a more development, stimulating the motor coordination in a general way, making children more timid that used to not participate in the activities performed outdoors to participate with more enthusiasm, more loose, and wanting every day new games, with the realization of the project, the group of children become - if more kingdom.

LONGITUDINAL STUDY OF MOTOR COORDINATION IN CHILDREN THROUGH THE PRIMARY EDUCATION

PALOMO, M., RUIZ, L.M.

UNIVERSIDAD POLITÉCNICA DE MADRID

Introduction: The difficulties of movement, the motor coordination problems or the developmental coordination disorders in Primary school children are alarming according to the latest research (Spittle, A. et al. 2018; Yu, J. et al. 2018), increasing the interest in the study of

this problem. Knowing what happens to them, at what point in their evolution such motor difficulties are more striking or if it lasts over time, are issues currently being addressed. The environment of the Physical Education class is ideal to carry out that evaluation, as well as the control of this evolution throughout the time. There are batteries that allow for establish the level of clumsiness or motor competence at the time of application. Although knowing their evolution over the time can favor the work with these children in Physical Education classes, as well as outside of them. Aim: Therefore, the goal of this research was to determine the level of motor competence and its evolution over a period of 6 academic years (Primary School 1st to 6th grade).
Methodology: The participants were 41 children (25 girls and 16 boys), all of them born in 2005 and who, therefore, were 6 years old at the time of the first application and 12 when the data collection was finished. The instrument used was the GRAMI battery (Ruiz, L.M., et al. 2015), applied to all children in a favorable environment for carrying out each of the tests. The tests were divided into 3 groups, always carrying out the same tests in the same month. So that, the aim of the study was to check the evolution on motor development in children by testing them throughout the years.
Results: To analyze the data it was run an ANOVA with repeated measurement in the last factor (gender X year). The results of this study show a significant evolution in the 8 tests: hop along 7 meters; 30 meters race; Medicine ball; roundtrip 9 meters race; Stand up/Lay Down; Horizontal Jump; Jumping Jacks; 3 meters brackets race. The analysis show how the children improve in every test along the years being significant the first year with the second, third, forth, fith and sithx year in every test regardless the gender. However, the data show how in the middle of the data collection the scores were not significant between the third and fourth year in every test. Regarding the gender, results show significant differences in this three tests: hop along 7 meters, stand up/lay down and the brackets race; showing higher scores the boys than the girls.
Discussion: The findings confirm the evolution of the motor development and how this test GRAMI could help in the diagnosis of some troubles and difficulties in terms of movement. The results of this study could explain and support the idea of evaluating children in a long term as an strategy to check difficulties of movement in children in Primary Schools.

Physiology

INTERMITTENT VASCULAR OCCLUSION IN UPPER LIMBS: IS IT AN EFFECTIVE WAY TO IMPROVE STRENGTH AND NEURAL FUNCTION?

PUGGINA, E.F., OLIVEIRA, L.P., AQUINO, R.L.Q., MANECHINI, J.P.V., CASTRO, F.M.P.
UNIVERSITY OF SÃO PAULO

INTRODUCTION:The available literature postulates that muscular strength is influenced by skeletal muscle hypertrophy and/or changes in neural drive, among others factors. Therefore, the relationships between skeletal muscle cross-sectional area and strength is well established. However, in some situations, e.g. in the beginning of the strength training, increases in strength may occur prior to significant hypertrophy, which suggests the influence of the neural drive, despite the increases of the cross-sectional area. This study investigated the chronic effects of 9-weeks (3 assessment weeks (pre; after 3 training weeks; post) + 6 training weeks not included familiarization session) low-intensity strength training with intermittent vascular occlusion (LIVO) on strength and electromyographic (EMG) parameters in the biceps brachii.
METHODS: Nineteen volunteers were separated in two groups: LIVO (n=10) and low intensity strength training without occlusion (LI) (n=9). The training consisted of three sets with 20% of one maximum repetition (1RM) with 90s of rest for both groups. Following variables were evaluated: predicted 1RM (through Brzycki equation), root mean square (RMS) and median frequency (MDF) of biceps brachii.
RESULTS: There were no changes in 1 RM after training protocol or between groups at any assessments ($p < 0.05$). RMS did not change after the protocol in neither group but was greater in LIVO than LI group in the 2nd and 3rd sets for both arms. MDF was similar between groups and was not influenced by training.
CONCLUSION: We concluded that LIVO is not a good technique to increase strength and to produce neural adaptations.

HIGH-INTENSITY INTERVAL TRAINING IMPROVES ERYTHROCYTE OSMOTIC DEFORMABILITY

WANG, J.
CHANG GUNG UNIVERSITY

INTRODUCTION:Physical exercise or hypoxic exposure influences erythrocyte susceptibility to osmotic stress. Aquaporin 1 (AQP1) channel facilitates the transport of water in erythrocytes. This study investigated whether high-intensity interval training (HIIT) and moderate-intensity continuous training (MICT) affect erythrocyte osmotic deformability by modulating AQP1 function under hypoxic stress.
METHODS: Forty-five healthy sedentary males were randomized to engage in either HIIT (3-min intervals at 40% and 80%VO2max, n=15) or MICT (sustained 60%VO2max, n=15) on a bicycle ergometer for 30 min/day, 5 days/week for 6 weeks, or to a control group that did not perform any exercise (n=15). Erythrocyte membrane stability and osmotic deformability following hypoxic exercise (HE) (100W under 12%O2 for 30 min) were analyzed with osmotic gradient ektacytometry.
RESULTS: Before the intervention, HE increased the shear stress at 50% of maximal elongation (SS1/2) and the ratio of SS1/2 to maximal elongation index (SS1/2/EImax) on erythrocytes pretreated with 50 Pa for 30 min and diminished HgCl2-depressed osmolality at 50%EImax (Ohyper). However, both HIIT and MICT for 6 weeks diminished the elevations of erythrocyte SS1/2 and SS1/2/EImax caused by HE. Moreover, HIIT also increased erythrocyte AQP1 level while enhancing HgCl2-depressed Ohyper and area under elongation index-osmolarity curve (AUC) following HE. Additionally, changes in erythrocyte AQP1 levels were associated with changes in HgCl2-depressed erythrocyte Ohyper and AUC.
CONCLUSION: Acute HE reduces erythrocyte membrane stability, whereas either HIIT or MICT attenuates the depression of erythrocyte membrane stability by HE. Moreover, HIIT increases the AQP1 content and facilitates the HgCl2-mediated osmotic deformability of erythrocytes following HE.

SLEEP CHARACTERISTICS OF ELITE ATHLETES OF THE RIO 2016 OLYMPIC GAMES

MELLO, M.T.1, NARCISO, F.V.1, TUFIK, S.2, ROSA, J.P.1, RODRIGUES, D.F.1, BICHARA, J.J.3, PEREIRA, S.3, SILVA, S.3, SILVA, A.1

1: UNIVERSIDADE FEDERAL DE MINAS GERAIS 2: UNIVERSIDADE FEDERAL DE SÃO PAULO 3: COMITÊ OLÍMPICO DO BRASIL

INTRODUCTION:Sleep is recognized as a key component for maintenance of physical and cognitive performance. The aims of this study were: 1) to analyze chronotype, duration and quality of sleep among elite athletes, 2) to compare differences in sleep variables between sex, and 3) to compare differences between athletes of individual and team sports.
METHODS: The sample included 70 Brazilian elite athletes of both sex with a mean age 23.0 years old. To measure sleep-wake cycles, athletes wore an actigraph on the wrist for 10 days. Moreover, athletes answered the chronotype questionnaire of Horne and Östberg.
RESULTS: The results demonstrated that most athletes are intermediate-type (n=55, 78.6%), with a mean of 07h:42min of sleep per night. The athletes demonstrated higher sleep fragmentation (39.26, s=23.66; IC95% =33.97 - 44.60) and difficulty sleeping (30.88, s=16.19; IC95% =27.46 -35.10) during pre-competition training days. Additionally, the athletes of individual sports demonstrated more fragmentation (t=3.85; p<0.001) and less sleep efficiency (t=4.53; p<0.001) compared to athletes of team sports.
CONCLUSION: Therefore, the elite athletes demonstrated poor sleep quality with increased awakenings and sleep onset latency during the training periods prior to the Rio 2016 Olympic Games.

THE ASSOCIATION BETWEEN BODY MASS INDEX AND MUSCULOSKELETAL PAIN IN FOUNDATION PHASE EDUCATORS

PILLAY, J.D., EGGARS, L.S., GOVENDER, N.

DURBAN UNIVERSITY OF TECHNOLOGY

INTRODUCTION:Evidence supports the association between body mass index (BMI) and musculoskeletal pain (MSP) with overweight/obese states being a significant predictor of MSP. This association may be related to vocation and the extent of musculoskeletal exertion therein.
Aim: To determine the association between BMI and MSP among foundation phase educators.
METHODS: Educators, classified as non-overweight (BMI≤24.9kg/m2) or overweight (BMI≥25kg/m2), were analysed for neck/shoulder pain (NSP) and low back pain (LBP) using a validated questionnaire. Logistic regression analyses presented odds ratios (ORs) and confidence intervals (CIs) on the association between BMI and MSP (age and gender adjusted).
RESULTS: Of 70 completed questionnaires , 35.7% (n=25) were within the non-overweight BMI range and 64.3% (n=45) were within the overweight/obese group. NSP was reported in 85.7% (n=60), 61.7% (n=37) of whom were in the overweight group. LBP was reported in 78.5% (n=55), 63.7% (n=35) of whom were in the overweight/obese group. Overweight individuals were more likely to experience NSP (OR: 2.486, 95% CI: 0.485-12.749) and LBP (OR: 1.143, 95% CI: 0.342-3.817).
CONCLUSION: Our findings highlight an association between BMI and MSP. These findings imply the need to explore worksite interventions, including workload/ergonomic considerations, that reduce MSP and promote a healthy BMI among staff.

ASSOCIATION OF SPORTS VISION WITH AGE, GENDER, AND STATIC VISUAL ACUITY

LIM, A.Y.1, LEE, J.S.2, LIU, Y.H.1,2, CHEN, W.M.1, LIN, K.K.2, CHANG, S.T.3, HOU, C.H.2, PENG, W.S.1, SEE L.C.1,2

1:CHANG GUNG UNIVERSITY, 2:CHANG GUNG MEMORIAL HOSPITAL, 3:CHUNG YUAN UNIVERSITY

INTRODUCTION:Excellent vision is essential to performing well in sports. Sports vision parameters including dynamic visual acuity (DVA), eye movement (EM), peripheral vision (PV), and momentary vision (MV). DVA has been frequently studied but not the other three parameters. The relationship of these sport vision with the static visual acuity is not clearly understood. Therefore, we examined how DVA, EM, PV, and MV varied with age and sex, and assessed the effect of static visual acuity (SVA) on sports vision performance.
METHODS: Sports vision was assessed at 45 cm in 310 participants (100 males; age, 6–60 years) using a commercially available software package (Athlevision; ASICS Corporation, Japan). Among these 310 participants, 108 non-athletic university students were further assessed their sport vision at 2.5 m with and without glasses in order to examine the effect of SVA on sports vision.
RESULTS: DVA was significantly associated with age in males and females. It increased during childhood, peaked during the 20s or 30s, and gradually decreased during middle age (p<0.0001). DVA was significantly better in males than in females (p=0.0001). The other 3 sport vision parameters—EM, PV, and MV—exhibited similar age trends (p<0.001) as DVA. Males and females did not differ in EM, PV, or MV (p=0.364, p=0.763, p=0.725, respectively). Among the 108 non-athletic university students, 17 were emmetropic, 26 had mild myopia, 24 had moderate myopia, 32 had severe myopia, and 9 had anisometropia. Among those with mild myopia, DVA, EM, and PV were similar at both near and far distances, with and without correction. However, DVA, EM, and PV were worse at 2.5 m than at 45 cm among those with moderate or severe myopia when their vision was uncorrected. There was no difference in MV in relation to experimental condition or refractive error.
CONCLUSION: Sport vision is best performed at age 20-30s. DVA is better in males. Static visual acuity has a definite effect on the performance of sports vision, especially in the far distance.

EFFECT OF RAIN ON THERMAL RESPONSES AND ENERGY METABOLISM WHILE RUNNING AT MODERATELY HIGH INTENSITY IN A COOL CONDITION.

ITO, R.

DAIDO UNIVERSITY

INTRODUCTION:Outdoor exercise often proceeds in rainy conditions (e.g. marathon, soccer and rugby). We previously showed that esophageal temperature decreases and oxygen consumption and plasma lactate concentrations increase while moderately running exercise in rain at 5 ˚C. However, there are a few studies have been reported on human physiological responses during exercise in rainy conditions. Additionally, to our knowledge, there has not been investigated on human physiological responses during moderately high

intensity exercise in cool rainy conditions. The purpose of this study was to investigate the effects of rain on physiological responses during running exercise at 70%VO2max at 10˚C.
METHODS: Eight healthy men [age, 21.3 ± 4.3 y; height, 170.3 ± 6.5 cm; mass, 66.1 ± 4.1 kg; VO2max, 59.3 ± 3.12mL/kg/min; means ± SD] who were non-smokers and not currently taking medication participated in this study. The participants rested for 10 min and exercised on a treadmill at 70%VO2max intensity for 60 min with rain (RAIN) or not (CON) at 10 ˚C. Head wind equal to running speed was brown during exercise at both trials. Trials were randomly assigned and balanced for order.
RESULTS: Rectal temperature was significantly lower in RAIN than that in CON at 10 min ($p<0.05$). Weighted mean skin temperature was significantly lower in RAIN than that in CON during exercise ($p<0.05$). Thermal sensation was significantly lower in RAIN than that in CON during exercise ($p<0.05$). Oxygen consumption was not significantly difference between RAIN and CON. Heart rate was significantly lower in RAIN than that in CON from 10 min to 50 min ($p<0.05$). Perceived exertion was not significantly difference between RAIN and CON. Plasma lactate was significantly higher in RAIN than that in CON at 10 min ($p<0.05$). Plasma norepinephrine were significantly higher in RAIN than that in CON at 10 and 20 min ($p<0.05$). Plasma glucose, plasma epinephrine, serum triglyceride and serum free fatty acid were not significantly difference between RAIN and CON. Respiratory exchange ratio was not significantly difference between RAIN and CON.
CONCLUSION: The lower rectal temperature, higher plasma norepinephrine and higher plasma lactate in RAIN indicate that rain increase the heat loss during early phase of exercise at 10 ˚C. Therefore, running performance might decline in the presence compared with the absence of cool precipitation.

EFFECTS OF EXERCISE AND RAPAMYCIN ON HEPATIC NF-KB IN RATS FED A HIGH-FAT DIET

LIAO, B.

GUANGZHOU SPORT UNIVERSITY

INTRODUCTION:Both mechanistic target of rapamycin (mTOR) signaling and inflammation contribute to obesity-related metabolic dysfunction. It has also been suggested that reduced mTOR and reduced NF-kB contribute to exercise-induced improvements in insulin resistance, but chronic administration of the mTOR inhibitor rapamycin aggravates high-fat diet induced-insulin resistance. We investigated if rapamycin alters exercise-induced changes in hepatic NF-KB signalling in high-fat diet (HFD)-fed rats.
METHODS: Male rats were fed a normal diet (n=6) or HFD (n=24) for 6 weeks. After one week of exercise adaptation, HFD rats were randomized into 4 subgroups (6/subgroup): HFD+sedentary (H), HFD+exercise (HE), HFD+rapamycin (HR), and HFD+ exercise+ rapamycin (HER). The HE and HER groups performed exercise training from 8th−11th week. Rat in HR and HER groups received intraperitoneal rapamycin (2 mg/kg/day) during 10th −11th week.At the 11th week, the glucose tolerance and insulin tolerance tests were performed two days before the sacrifice of the animals. Finally, the rats were sacrificed after 12-16 hour fast. Westernblotting were used to determine the level of S6,P-S6 ,NFKB,IkB and nulcear NFKB in liver.
RESULTS: The exercises and rapamycin reduced the body weight and relative body fat ($P< 0.05$). Moreover, the exercises improved the glucose tolerance and insulin tolerance while the rapamycin aggravated these indices. Further analysis indicated that the exercise significantly reduced both P-S6 level and NF-kB activity in liver, but rapamycin increased hepatic NF-kB activity in HFD rats.
CONCLUSION: Rapamycin upregulates hepatic NF-kB activity in HFD rats. Our data suggest that increased NF-kB activity may contributes rapamycin-aggrevated insulin resistance.

EFFECT OF INCREASED CALF VENOUS COMPLIANCE WITH WEARING GRADUATED COMPRESSION STOCKINGS ON CIRCULATORY RESPONSES DURING THE RECOVERY PERIOD AFTER EXERCISE IN YOUNG PEOPLE

OUE, A., IIMURA, Y.

TOYO UNIVERSITY

INTRODUCTION:Graduated compression stockings (GCS) increased calf venous compliance at rest in healthy young people (1). However, the effect of increased calf venous compliance with wearing GCS on circulatory responses during the recovery period after exercise remains unclear. Considering that GCS may improve functionality of the skeletal muscle pump (2) and may increase deep venous velocity and/or decrease blood pooling in the calf veins (3), it is hypothesized that circulatory responses during the recovery period after exercise might return to baseline level faster under conditions of increased calf venous compliance with wearing GCS rather than not wearing GCS, and the degree of benefit from GCS might be greater during the recovery period with exercise rather than recovery period at rest. Thus, the purpose of this study was to clarify the effect of increased calf venous compliance with GCS on circulatory responses during the recovery period at rest or with exercise.
METHODS: Seven young healthy volunteers (5 men, 2 women; mean age 21.1 ± 0.9 [SD] years) participated in this study. In a preliminary experiment, we assessed calf venous compliance at rest by measuring calf venous volume with or without GCS using venous occlusion plethysmography. Participants were placed supine while a venous collecting cuff placed around the thigh was inflated to 60 mmHg for 8 min, and then cuff pressure was decreased to 0 mmHg at a rate of 1 mmHg/s. Venous compliance was calculated as the numerical derivative of the cuff pressure and venous volume curve. Venous capacitance and maximal venous outflow were also determined from the changes in venous volume during inflation and deflation of the cuff. In the main experiments, participants performed 5-min cycling exercise at 60% of heart rate reserve and then had a 5-min active recovery period involving exercise at 10 W or a 5-min resting recovery period involving only rest. This protocol was carried out either while wearing (GCS group) or not wearing stockings (no-GCS group) on separate days. Heart rate, blood pressure, forearm blood flow, and forearm vascular resistance were then measured.
RESULTS: Wearing GCS increased venous compliance, venous capacitance, and maximal venous outflow in the calf. However, circulatory responses during both active and resting recovery periods did not differ between the GCS and non-GCS groups.
CONCLUSION: Increased calf venous compliance with wearing GCS had no significant effect on circulatory responses during active or resting recovery period after short-term cycling exercise in healthy young people.

EFFECTS OF ACUTE SWIMMING EXERCISE ON PGC1ALPHA-IRISIN-UCP1 SIGNALING PATHWAY

EUN HEE, C.H.O., CHAE EUN, C.H.O., SEWON, L.E.E.

INCHEON NATIONAL UNIVERSITY

INTRODUCTION:Exercise induces an increase in peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1α), which stimulates expression of fibronectin type III domain-containing protein 5 (FNDC5) in skeletal muscles. As a result, FNDC5, a membrane protein, is cleaved and released as a form of irisin in the circulation. It has been shown that circulating irisin stimulates uncoupling protein1 (UCP1) which increase energy expenditure in white adipocytes. It is not clear whether irisin and related signaling proteins is changed through acute exercise. Therefore, we sought to test the hypothesis that acute swimming exercise will induce alterations in the expression of irisin and related factors.
METHODS: Male C57BL/6 mice(n=20) were randomly assigned to 2 groups: control group (CON), swimming exercise group (SEG) for 90 minutes. After the acute exercise, we collected the serum, adipose tissues, and skeletal muscles and assessed mRNA and protein expression of PGC1α, FNDC5 and UCP1, and circulating irisin level.
RESULTS: Neither soleus nor gastrocnemius muscles affected expression of PGC1α, after exercise, even though expression of FNDC5 was increased in both muscle tissues. The mRNA expression of FNDC5 was significantly increased in soleus of SEG compared to CON($p<.05$), whereas it was not changed in the gastrocnemius muscle. However, the protein expression of FNDC5 was significantly increased in SEG compared to CON in the gastrocnemius muscle($p<.05$). The protein expression of UCP1 tended to be higher in the SEG than in the CON, but it was not statistically significant in the both brown and white adipose tissue. The circulating irisin level was significantly increased in the SEG compared to CON. ($p<.01$)
CONCLUSION: Irisin is exercise-induced myokine and acute swimming exercise caused alterations in the expression of irisin and related signaling proteins.

RELATIONSHIP BETWEEN RESPIRATORY MUSCLE FUNCTIONS AND AEROBIC / ANAEROBIC EXERCISE PERFORMANCE AND VENTILATORY RESPONSE DURING EXERCISE IN COMPETITIVE SWIMMERS

MURANAKA, M.

UNIVERSITY OF TSUKUBA

INTRODUCTION:Because of its specific aquatic environment, breathing is restricted in swimming. For example, respiration must be synchronized with the arm stroke so that swimmers have to inhale quickly in a short time. Also, swimmers need to expand the chest against hydrostatic pressure for inspiration. As a result, swimming requires extra work in inspiration than in land-based sports. However, the relationship between respiratory muscle functions and exercise capacity in competitive swimmers are not clear. Therefore, the aim of this study was to clarify the relationship between respiratory muscle strength and aerobic / anaerobic exercise capacity and ventilatory response during exercise in competitive swimmers.
METHODS: In this study, respiratory muscle functions measurements (PEmax, PImax, FVC, FIV0.5 and MVV) and aerobic and anaerobic cycling exercise tests were conducted in the group of well-trained competitive swimmers. Cycling exercise was selected to avoid the technical influence of swimming. For exercise tests, constant load exercise at 95%VO2peak load as an aerobic exercise and Wingate test as an anaerobic exercise were performed. During exercise tests, ventilatory response and the exercise performance were assessed.
RESULTS: The participants showed higher respiratory muscle functions including higher inspiratory muscle strength than the values of other athletes in the previous researches. Respiratory muscle strength such as PImax and PEmax per body weight had no significant correlation neither with ventilatory response nor exercise performances. However, respiratory muscle functions such as FVC and FIV0.5 had significant correlation with exercise tolerance time of constant load exercise test and the ventilatory response during this test. Also, FVC, FIV0.5 and MVV had significant correlation with ventilatory response during anaerobic exercise test and peak and mean power during Wingate test.
CONCLUSION: It is indicated in previous studies that when tidal volume increases at the same ventilatory volume during exercise, the respiratory work will be decreased, therefore it would lead to exercise performance improvement. In this research, significant correlations were found between respiratory muscle functions and the peak tidal volume during exercise and the exercise performances. These findings suggest that not respiratory muscle strength, but other respiratory muscle functions may play an important role on the exercise performance. But further research is needed to clarify whether improvement of respiratory muscle functions could enhance exercise performance or not. Concerning the strength of correlations, FVC and FIV0.5 showed stronger correlations between ventilatory volume and tidal volume during aerobic exercise than during anaerobic exercise. Therefore, respiratory muscle functions would be more important for the aerobic energy supply system. The findings in this research could be a clue to clarify the relationship between respiratory muscle functions and swimming performance.

EXTRACELLULAR VESICLES AS REGULATOR OF MYOGENESIS

KANG, J.H., PARK, H.D., KIM, C.S.

INHA UNIVERSITY COLLEGE OF MEDICINE

INTRODUCTION:Skeletal muscle is the largest organ in the body of non-obese human, and plays key roles in whole-body metabolism. Therefore, inflammation in skeletal muscle is important in the development of insulin resistance, aging, and chronic diseases including cancer cachexia and congestive heart failure. Furthermore, these pathologic conditions with acute or chronic muscle inflammation lead to physical inactivity and aggravate loss of skeletal muscle oxidative capacity, and vice versa. Recently, skeletal muscle is also a secretory organ, which by secretion of muscle cell-derived effector molecules, 'myokines' may regulate skeletal muscle metabolism and differentiation through intercellular communication. Given that a number of myokines was found in secretory intercellular communicating vesicle, the regulation of myogenesis by inflammation through the secretory vesicles has not been elucidated. Therefore, we hypothesized that inflammation alters myokine expression in skeletal muscle cells, and extracellular vesicles released from inflammatory muscle cells may be responsible for suppressing muscle differentiation.
METHODS: Inflammation was induced by treatment of fully differentiated C2C12 myotubes with a cytokine mixture of TNF-alpha and INF-gamma. Exosome-like extracellular vesicles (ELVs) were isolated from conditioned media of control or inflamed myotubes, and myoblasts were incubated with ELVs. Expression of molecular switches contributing myogenic differentiation including several kinases, their downstream target, and myokines were evaluated using immunoblot analysis in inflamed myotubes and in myoblasts treated with ELVs.

RESULTS: Inflammation activated molecular mechanisms contributing to muscle atrophy, including AMPK, p-38 MAPK and JNK, while inhibiting Akt-mediated myogenic signals. In addition, inflammation induced myostatin expression with suppression of a myostatin-counteracting myokine, decorin. Well-characterized ELVs released from inflamed myotubes induced myoblast inflammation and inhibited myogenic mechanisms (i.e., Akt, decorin) while stimulating atrophic signals (i.e., JNK, P70-S6K, MAFbx).
CONCLUSION: In this study, although the molecular components that regulate myogenesis in ELVs released from myotubes should be further identified, our results provided, at least in part, evidence that inflammatory ELVs contribute to the inhibition of myoblast differentiation via multiple mechanisms, including disinhibition of the Akt-mediated suppression of FOXO3-MAFbx transcription, activation of the AMPK, p38-MAPK, and JNK signaling pathways, and induction of inflammation. Further characterization of the molecular components of ELVs is warranted for the elucidation of mechanism underlying inflammation-induced muscle atrophy.

DECREASES IN RESISTANCE EXERCISE SBP BY AEROBIC TRAINING IS ASSOCIATED WITH NITRIC OXIDE IN OLDER INDIVIDUALS

OTSUKI, T., NAKAMURA, F., ZEMPO-MIYAKI, A.

RYUTSU KEIZAI UNIVERSITY

INTRODUCTION:Aerobic exercise training decreases systolic blood pressure (SBP) during resistance exercise, an early marker of cardiovascular disease, in middle-aged and older individuals (Otsuki et al., 2016). Animal studies suggest that nitric oxide (NO), an endothelium-derived vasoactive factor, is related to aerobic training-induced enhancement in blunting of sympathetic vasoconstriction during exercise (functional sympatholysis). This study investigated whether aerobic training-induced decreases in SBP during resistance exercise is associated with NO in older individuals.
METHODS: Community-dwelling middle-aged and older individuals participated in a 6-week intervention as a part of the training (walking, 3 to 5 d/wk, 30 to 60 min/d, 65 to 75% of maximal heart rate) or control group.
RESULTS: SBP during one-hand arm curl exercise at 20 and 40% of one repetition maximum and brachial-ankle pulse wave velocity (baPWV, an index of arterial stiffness) decreased after the intervention in the training group. In addition, aerobic training increased plasma concentrations of nitrite/nitrate (NOx, end product of NO). Changes in SBP during resistance exercise were correlated with those in plasma NOx concentrations and baPWV.
CONCLUSION: Decreases in resistance exercise SBP by aerobic training may be associated with NO in older individuals.

ABERRANT CARDIOPULMONARY FUNCTION DURING EXERCISE TESTING AND EXERCISE INTOLERANCE IN RELATION TO CARDIOMETABOLIC HEALTH IN OBESE ADOLESCENTS

FRANSSEN, W., SPRUIT, M.A., BEYENS, M., MARINUS, N., BERVOETS, L., VIJGEN, J., KOOPMAN, P., HEIDBUCHEL, H., VERBOVEN, K., EIJNDE, B.O., DENDALE, P., MASSA, G., HANSEN, D.

HASSELT UNIVERSITY

INTRODUCTION:In adults with obesity aberrant cardiopulmonary functions are often observed. However, it remains controversial whether cardiopulmonary disturbances could be observed consistently in adolescents with obesity. Therefore, the purpose is to compare cardiopulmonary parameters during exercise between obese and lean adolescents, and to examine associations between altered cardiopulmonary parameters, or exercise intolerance, and cardiometabolic health.
METHODS: Sixty obese (moderate obese: n=31, BMI=29.5±2.3kg/m2; severe obese: n=29, BMI=37.1±3.8kg/m2) and 44 lean adolescents (n=44, BMI=19.1±2.2kg/m2) performed maximal cardiopulmonary exercise testing (CPET) with comparison of cardiopulmonary exercise parameters. Haematology, biochemistry and endocrine hormones were studied in fasted blood samples. Regression analyses were applied to examine relations between altered CPET parameters or exercise intolerance and subject characteristics, blood parameters or ECG variables.
RESULTS: Peak work rate (WRpeak), oxygen uptake (P'O2peak)/WRpeak, mechanical efficiency, respiratory frequency and minute ventilation were significantly lowered ($p<0.05$) in adolescents with obesity. A lowered WRpeak was independently related to an elevated blood leptin concentration and triglyceride-to-HDL cholesterol ratio ($p<0.05$). A lowered ȦO2peak/WRpeak was independently related to an altered fasting glucose concentration, triglyceride-to-HDL cholesterol ratio and QRS-width ($p<0.05$). The mechanical efficiency, minute ventilation and respiratory frequency were independently related to elevated blood leptin concentrations ($p<0.05$).
CONCLUSION: Conclusion: In adolescents with obesity, especially WRpeak, ĊO2peak/WRpeak, mechanical efficiency and ventilation were suboptimal during CPET. These alterations were independently associated with a worse blood lipid profile, hyperleptinemia and hyperglycaemia.

EVALUATION OF EXERCISE-TO-REST RATIOS DURING ELITE MEN'S ULTIMATE FRISBEE MATCHES

DI MICHELE, R., MORRI, D.

UNIVERSITY OF BOLOGNA

INTRODUCTION:Ultimate frisbee is a fast growing team sport played with a flying disc on a 100x37 m grass pitch by two teams of 7 players. Despite the increasing popularity of this sport, there is still a paucity of research on the physical demands of match play in competitive players. Moreover, previous data were assessed on sub-elite players using an ad-hoc game, and thus under different competitive conditions from those occurring in official matches (1). To contribute to a more in-depth understanding of the physical demands of elite men's ultimate frisbee, this study aimed to assess the exercise-to-rest ratios during top-level matches played in recent international tournaments.
METHODS: The video footage of three men's matches was used for the analysis. The matches were the final of the 2016 World Ultimate and Guts Championship, the final of the 2017 U24 World Ultimate Championship, and the final of the 2018 World Ultimate Club Championship. A total of 86 points were played in the three matches. For every point, an experienced coach recorded the start (throw-off by the defending team) and end (goal scored) time points. Furthermore, time points were recoreded corresponding to all events when a phase of active play started (e.g., disc check or self-check) or ended (e.g., disc on the ground or out of field, foul call, etc.). Subsequently, the

duration of exercise and rest periods (excluding times out and periods between points) was calculated and their distribution was assessed.
RESULTS: The average number of exercise and rest periods per point was, respectively, 2.7 and 1.5. The distribution of both exercise and rest periods was strongly exponential, with higher proportion of shorter than longer periods. The median and interquartile range of duration for exercise and rest periods were, respectively 21 (12 to 34) s, and 16 (10 to 26) s. On average, the exercise-to-rest ratio was 1.94:1, that is, an average of 66% and 34% of total time within points was respectively spent exercising and resting.
CONCLUSION: The present data highlight the intermittent nature of ultimate frisbee match play, with short bouts of high-intensity exercise interspersed, during a point, by resting periods of slighlty shorter duration. Nevertheless, since there are quite long pauses between points (80 s on average), and players can be substituted without a limit after the end of any point (elite teams are composed by up to 28 players), a single player may be involved in active play for a total of less than 5 min out of a total match duration of 100 min in a balanced match at elite level. In conclusion, from a physiological perspective, the capacity of repeating short, near-to-maximal exercise running bouts and to restore energy during the subsequent recovery periods (including non-playing periods on the pitch sideline), would seem key factors for performance in competitive ultimate frisbee.

INFLUENCE OF AEROBIC FITNESS ON INHIBITORY CONTROL AND PREFRONTAL BRAIN OXYGENATION IN ADOLESCENTS

MUECKE, M., LUDYGA, S., PUEHSE, U., GERBER, M.

UNIVERSITY OF BASEL

INTRODUCTION:The degree of aerobic fitness can have an influence on higher cognitive functions and change activity patterns in relevant brain regions. Recent research showed that in adults higher levels of fitness are associated with better inhibitory control and higher oxygenation of the right inferior frontal gyrus (Dupuy et al., 2015) and the dorsolateral prefrontal cortex (DLPFC; Albinet et al., 2014). However, it is unclear if similar patterns can be found in younger age groups as well.
METHODS: 43 healthy, male, right-handed participants aged 16-20 years performed a computerized Stroop Color-Word task. Lower stroop interference (reaction time in incompatible trials minus compatible trials) represented better inhibitory control. Simultaneously, 23-channel functional near-infrared spectroscopy (fNIRS) was used to measure oxygenation in the prefrontal cortex. Aerobic fitness was determined using the Physical Working Capacity 170 test (PWC170, (Bland, Pfeiffer, & Eisenmann, 2012)). A median split was used to separate fitter (Group 1) and less fit (Group 2) participants.
RESULTS: Group 1 (3.4 +/- 0.4 W/kg) showed a significantly higher aerobic fitness than Group 2 (2.5 +/-0.3 W/kg; $t(41) = 8.30$, $p < .001$). Interference was significantly higher in Group 2 (56.9 +/- 44.9 ms) compared to Group 1 (27.1 +/- 36.5 ms; $t(41) = -2.40$, $p = .021$), indicating better inhibitory control in fitter participants. Cluster based permutation testing revealed significant group differences in channel 10 representing brodmann area 46 (left DLPFC), with higher oxygenation during the incompatible condition and lower oxygenation during the compatible condition in fitter participants.
CONCLUSION: Our data suggest that physically fitter adolescents show better inhibitory control than their less fit peers. In line with previous studies, this was accompanied by differential activity patterns in the left DLPFC.

CHANGES IN PLASMA VISFATIN CONCENTRATION UPON EXTREME PHYSICAL LOAD IN HUNGARIAN ATHLETES

FAR, G., LIGETVÁRI, R., CSÖNDÖR, É., MÓRA, Á., TÓTH, M.V., TÓTH, M., ÁCS, P., OLÁH, A.

1 UNIVERSITY OF PÉCS FACULTY OF HEALTH SCIENCES, PÉCS , 2 SEMMELWEIS UNIVERSITY, BUDAPEST, 3 UNIVERSITY OF PHYSICAL EDUCATION, BUDAPEST, 4 ELTE FACULTY OF PEDAGOGY AND PSYCHOLOGY

INTRODUCTION:Visfatin is a cytokine that is mainly synthesized in visceral fat but it can be found in the liver, bone marrow and muscles, as well. It is an adipokine associated with obesity, involved in inflammatory phenomena and insulin secretion. Visfatin reduces insulin resistance and the apoptosis of activated neutrophils. The N-terminal proBNP is a molecule that is used to characterized left ventricular function. The normal level of Nt-proBNP indicates intact ventricular function. The aim of the research is to examine how the concentration of plasma visfatin changes in athletes as a result of physical stress.
METHODS: The physical load was a vitamaxima type treadmill test. The protocol included fixed incline and steadily rising speed. We recorded the changes in blood pressure (BP), heart rate (HR), respiratory parameters (VO2 max) and lactate concentration of 27 athletes (mean age: 27 years). Blood samples were taken at three different times: before the treadmill test, at maximum load and 30 minutes after the peak load. We analyzed plasma visfatin (VF: Elabscience) and plasma N-terminal proBNP (NT-proBNP: Biomedica) values by ELISA.
RESULTS: Systolic blood pressure measured in three differnet times was: 142 ± 12 mmHg, 178 ± 18 mmHg, 128 ± 10 mmHg, respectively. Dyastolic blood pressure measured in three differnet times was: 81 ± 8 mmHg, 79 ± 11 mmHg, 74 ± 8 mmHg, respectively. The heart rate measured in three different times was: 72 ± 14 beats/min, 189 ± 9 beats/min, 86 ± 11 beats/min, respectively. Lactate levels at peak load were significantly ($p<0.05$, $p=4.10*10^{-29}$) increased (11.4 ± 2.3 mmol / L) compared to baseline levels (0.89 ± 0.31 mmol / L). There was significant ($p<0.05$) difference between baseline and peak visfatin level (baseline: 4.02 ± 2.7 ng / ml vs. peak: 5.22 ± 3.35 ng / ml, $p= 0{,}000378104$) and peak and recovery visfatin level (peak: 5.22 ± 3.35 ng vs. 3.53 ± 2.75 ng / ml, $p=3{,}27681*10^{-6}$). Plasma concentrations of N-terminal proBNP didn't change in a statistically significant way. During physical activity no arrhythmia was detected on ECG images.
CONCLUSION: Circulatory, respiratory and metabolic parameters of the subjects increased during the spiroergometric loading to total exhaustion. Plasma levels of N terminal BNP remained unchanged, indicating healthy left ventricular function. Serum visfatin levels were elevated significantly. The possible role of visfatin in the metabolic adaptation to acute physical stress needs further investigation.

EFFECTS OF WARMING OR COOLING OF THE UNILATERAL ARM ON MODULATIONS OF BRACHIAL ARTERY SHEAR STRESS AND ENDOTHELIAL FUNCTION DURING LEG EXERCISE IN HUMANS

FUKUBA, Y.

PREFECTURAL UNIVERSITY OF HIROSHIMA

INTRODUCTION:It is well recognized that leg cycling exercise induces endothelial adaptation of the conduit artery in an inactive limb (i.e., brachial artery; BA) beyond the active lower limbs (i.e., the leg). Such beneficial effects on the endothelium may be because of exercise-induced elevated shear stress (SS) due to increased blood flow to the BA. Modulation of the SS profiles, such as the pattern of antegrade and retrograde SS, is especially important for vascular adaptation. Elevations in the antegrade SS have positive effects, whereas elevations in the retrograde SS have negative effects. Warming of the arm (i.e., forearm and hand) is often used as an experimental manipulation to modulate the SS profile in the BA, thereby improving flow-mediated dilation (FMD) via shear-dependent mechanisms. In contrast, arm cooling adversely reduced the antegrade SS and increased the retrograde SS during exercise. To the best of our knowledge, the effect of arm warming during leg exercise on the SS patterns and FMD of BA remain known. Therefore, the aim of this study was to examine the effect of modulating the SS profile using forearm warming and cooling on the subsequent endothelial function in the BA during exercise.
METHODS: We recruited 12 healthy young subjects and immersed their right forearm into water at a temperature of either 15 °C or 42 °C during the leg cycling exercise at an intensity corresponding to a heart rate of 120–130 bpm for 60 min. As a control trial, the subjects performed the same exercise, but without water immersion. The BA diameter and blood velocity were simultaneously recorded using Doppler ultrasonography to evaluate the antegrade, retrograde, and mean shear rates (SR, an estimate of SS) before, during, and after the exercise. Furthermore, the endothelial function in the right BA was evaluated by means of FMD (%) using three-dimensional high-resolution ultrasonography before (baseline) and after the exercise (at 15 and 60 min).
RESULTS: During the exercise, compared with the control trial, higher antegrade and mean SRs and lower retrograde SR were observed than in the warm immersion trial. Conversely, lower antegrade and mean SRs and higher retrograde SR were observed in the cool immersion trial. After the exercise, there was no significant change in the FMD from the baseline in the warm immersion (but tended to increase) and control trials. However, in the cool immersion trial, the post-exercise FMD at 60 min decreased from the baseline (baseline 5.9%, cool 3.2%, $P < 0.05$) and was lower than the warm and control trials. The accumulated changes (area under the curve) in each SR during and after the exercise were significantly correlated with the change in post-exercise FMD.
CONCLUSION: Concomitant forearm cooling during leg exercise attenuates post-exercise endothelial function. The modulation of shear patterns in the BA during exercise appears to be associated with subsequent endothelial function.

JET-LAG SYMPTOMS IN JUNIOR ATHLETES AND THEIR RELATION TO PERFORMANCE

TSUKAHARA, Y., TABATA, S., YAMASAWA, F., MATSUMOTO, H.

KEIO UNIVERSITY

INTRODUCTION:Although many elite athletes go abroad for international competitions and training nowadays, junior athletes may find it difficult to adapt to new environment because of their paucity of experience. Little has been studied, however, about the effects of travelling to a foreign country on junior athletes and their response to them. Furthermore, studies regarding symptoms of jet lags and their relation to performance are very limited. Thus, our purpose was to evaluate their symptoms of jet lags and find out their relation to sports performance.
METHODS: Japanese junior track-and-field athletes participating in an international competition traveling westwards were enrolled in this study. Time difference between Japan was 7 hours. They filled a questionnaire regarding performance, sleep problems, appetite, fatigue and jet-lag, during their stay before they went to bed. The answers were scored by visual analogue scale from -5 (very negative compared to usual status, which is scored as 0) to 5 (very positive compared to usual status). Data were compared using Pearson parametric analysis.
RESULTS: Total of 46 athletes (26 boys and 20 girls) participated in this study. Athletes' performances had positive correlation to the followings; quality of sleep ($r=0.311$, $p<0.05$), motivation ($r=0.561$, $p<0.01$), concentration ($r=0.736$, $p<0.01$), easiness to sleep ($r=0.531$, $p<0.01$), mood ($r=0.612$, $p<0.01$), awakening ($r=0.320$, $p<0.05$), meal satisfaction ($r=0.343$, $p<0.05$) and amount of sleep they usually take per day ($r=0.343$, $p<0.05$).
CONCLUSION: Although there are many symptoms of jet lags, in our study, the symptoms that were mostly correlated to performances were those related to sleep problems and mental issues. Thus, it could be important for the athletes to take into account of the symptoms of jet lag and prepare for them in order to perform well.

EFFECTS OF A SINGLE BOUT OF MODERATE EXERCISE ON SUBSEQUENT PHYSICAL ACTIVITY OF MICE

QUINTANILHA, A.C.S., SANTOS, R.L.O., BENFATO, I.D., DE OLIVEIRA, C.A.M.

UNIVERSIDADE FEDERAL DE SÃO PAULO - CAMPUS BAIXADA SANTISTA

INTRODUCTION:The effects of exercise on energy balance is commonly below than expected. One possible explanation is that exercise may lead to a subsequent reduction in physical activity. Thus, the aim of our study was to evaluate whether a single bout of moderate exercise in mice influence cage physical activity in the following 48h. We also assessed whether the impact of exercise on physical activity changes as mice age from mature adulthood to the transition to middle age.
METHODS: Male C57bl/6 (n=10) mice (ethics committee CEUA 5541040218) were evaluated at 4 (4M) and 9 months of age (9M). Mice were submitted to a Maximal Exercise Capacity Test (MECT) in treadmill. After an interval of one week they performed a 30-min single bout of exercise at 50% of the maximal speed obtained in the MECT. Cage physical activity (PA) and average speed of locomotion (ASL) were determined individually by an infrared based system (IR Actimeter, PanLab) before (basal) and immediately after exercise for 48h (0-24h D1; 24-48h D2). Food intake was also registered. Results are expressed as mean +/- SE. Data was analyzed by repeated measure GLM. A significance level of $p<0.05$ was adopted.
RESULTS: Maximal speed at the MECT was similar at 4 and 9 months (4M=52.5 +/- 2.5; 9M=54.0 +/- 2.4 cm/s). PA decreased significantly in the first 24h hours after exercise but returned to basal level between 24-48h at 4 (basal=90,569 +/- 5,104; D1=59,212 +/- 5,803*; D2=82,668 +/- 7,202 counts) and 9 months (basal=74,775 +/- 6,161; D1=53,941 +/- 4,348*; D2=71,601 +/- 3,987 counts). ASL also decreased in the first 24h and remained lower than basal 24-48h after exercise at 4 (basal=0.52 +/- 0.05; D1=0.25 +/- 0.03*; D2=0.44 +/- 0.04* cm/s) and 9 months (basal=0.45 +/- 0.03; D1=0.26 +/- 0.03*; D2=0.38 +/- 0.02* cm/s). In D1, the magnitude for PA (4M=65.0

+/- 2.6; 9M=72.9 +/- 3.3*% of basal) and ASL reduction (4M=47.8 +/- 3.0; 9M=59.7 +/- 3.3* % of basal) was greater at 4 than at 9 months of age. No difference was observed in D2. Exercise had no effect on food intake.
CONCLUSION: A single bout of moderate exercise decreases subsequent physical activity in the first 24h and average speed of locomotion in the 48h following exercise in mice. The decreases in both the amount and intensity (speed) of PA may compensate for the increase in energy expenditure induced by exercise, helping to understand the below-than-expected effect of exercise interventions to cause a negative energy balance.

RESISTANCE EXERCISE MODIFIES MIRNA EXPRESSION RELATED TO MUSCLE ATROPHY DURING UNLOADING INDUCED BY 90 DAYS BED REST

CADEFAU, J.1,2, PÁRRIZAS, M.3, NOVIALS, A.3, GUERRERO, M.3, IRIMIA, J.M.4, TESCH, P.A.5, CUSSÓ, R.2

1: INEFC , 2: UNIVERSITAT DE BARCELONA , 3: IDIBAPS 4: INDIANA UNIVERSITY . 5. KAROLINSKA INSTITUTE, .

INTRODUCTION:Skeletal muscles undergo dramatic changes in metabolism, fibre composition and gene expression when exposed to microgravity during extended periods of spaceflight. Prolonged bed rest is a good approximation to model muscle degeneration occurring during spaceflight (1). Previous data from our group have shown that 90 days bed rest induced a decrease in aerobic metabolism and a loss of slow twitch fibres, accompanied by a loss of mitochondrial enzymes at both the mRNA and protein levels (2, 3). Exercise performed during the period of bed rest was able to partially counteract those changes. MicroRNAs (miRNAs) are small, non-coding RNA molecules that regulate gene expression at a post-transcriptional level and play a central role in the response of cells to stress, suggesting that they may regulate some of the expression changes occurring in muscle atrophy.
Our objective was to determine the changes taking place in skeletal muscle miRNA expression after prolonged bed rest in humans, and the effectiveness of concurrent resistance exercise to counteract them.
METHODS: 21 healthy participants were randomly divided into two groups: group 1 (BR, n=12) rested in bed for 90 days; whereas group 2 (BRE, n=9) followed a concentric-eccentric resistance protocol during bed rest (3). Percutaneous biopsies were obtained from the vastus lateralis before and after either intervention. Total RNA was extracted with Trizol and miRNA expression was profiled in 6 samples from each group by RT-PCR as described (4). Expression values were normalized to the levels of SNORD38B and SNORD49A.
RESULTS: Of the 372 individual miRNAs analysed, 120 (33%) were detected in all samples. Of those, a surprisingly elevated proportion (21%, 25 miRNAs) were significantly down-regulated in the BR group after the intervention. Decreased expression of miR-499a and the miR-30 family in our model is associated with a slow-to-fast fiber switch and increased glycolysis. miR-23a-3p and miR-27b-3p inhibit muscle atrophy by targeting atrogin I and myostatin respectively. Their down-regulation after bed rest is associated with increased atrophy. Interestingly, concurrent resistance exercise markedly attenuated those effects.
CONCLUSION: These results suggest that resistance exercise counteract at list in part the effects of 90 days of prolonged unloading. Specially, resistance exercise provokes increases of miR-27b and miR-23a. Strikingly, as is the case for the metabolic and physiological parameters, some of these miRNA expression changes were prevented at least in part by concurrent performance of resistance exercise.

REGIONAL DIFFERENCES IN DAMAGE AMONG THE HAMSTRING MUSCLES AFTER A FULL MARATHON

HIGASHIHARA, A., NAKAGAWA, K., INAMI, T., FUKANO, M., IIZUKA, S., MAEMICHI, T., HASHIZUME, S., NARITA, T., HIROSE, N.

WASEDA UNIVERSITY

INTRODUCTION:Prolonged running, such as marathon, has become more familiar sports activity for health promotion. However, marathon races are often reported to induce muscle damage in lower extremity muscles [1]. This study aimed to examine whether there are inter- and intramuscular differences in damage to the hamstring muscles after a full marathon using transverse relaxation time (T2)-weighted magnetic resonance images (MRI).
METHODS: Twenty healthy collegiate marathon runners (male, 15; female, 5) participated in a full marathon race. Maximal isometric knee flexion torque and T2-MRI of the thigh were obtained before (PRE) and 1 day (D1), 3 days (D3) and 8 days (D8) after the full marathon. T2 values of each muscle constituting the hamstring muscles at the middle (50 % of the thigh length), proximal (8 cm proximal of the middle site) and distal (8 cm distal of the middle site) sites were calculated. Absolute T2 values (ms) were used in between-time comparisons for each site. In addition, magnitude of T2 change was calculated by subtracting the baseline (PRE) value from the peak value after the marathon for each site, regardless of the time point that the peak value occurred, and was used for between-site comparisons.
RESULTS: Knee flexion torque significantly decreased from its baseline (PRE) value on D1 ($p = 0.007$) and D3 ($p = 0.009$). T2 significantly increased at the distal and middle sites of the hamstring muscles on D1 and/or D3 post running. Statistical significance was found at the distal biceps femoris long head on D1 ($p = 0.005$) and D3 ($p = 0.009$), middle biceps femoris long head on D1 ($p = 0.029$), distal biceps femoris short head on D1 ($p = 0.047$), distal semitendinosus on D1 ($p = 0.011$) and D3 ($p = 0.024$), middle semitendinosus on D1 ($p = 0.048$), and distal and middle sites of the semimembranosus on D1 ($p = 0.01$ and $p = 0.032$, respectively) and D3 ($p = 0.009$ and $p = 0.032$, respectively). There was no significant difference in magnitude of change in T2 between muscles at any site.
CONCLUSION: The results indicate that marathon running induces significant damage to hamstring muscles; site-dependent changes in T2 value within muscles after a full marathon were observed, including pronounced inflammatory oedema in the distal and middle sites of the hamstring muscles. However, the amount of change in T2 did not differ among the hamstring muscles. Our findings provide a better comprehension of the site-specific muscle damage patterns of the hamstring muscle induced by a full marathon.

PROTECTIVE EFFECT CONFERRED BY DOWNHILL RUNNING EXERCISE OF THE KNEE EXTENSORS

LIN, M.J.1, WU, S.H.1, CHEN, H.L.1, CHEN, T.C.2

1NATIONAL CHIAYI UNIVERSITY, 2 NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION:It has been documented that the first bout of downhill running (DHR1) induced muscle damage (DHRIMD) and the attenuated changes in MD parameters (1). It then started to recover gradually, and had returned to baseline by 4-6 days after DHR1. However, the second bout of the same DHR (DHR2) was performed after DHRIMD, DHR2 attenuated changes in marks of MD were smaller than DHR1. The previous study has reported the extent of MD for the initial exercise bout (bout1) of the elbow flexors, and the greater the magnitude of protective effect against a subsequent bout (bout2) of maximal eccentric contraction training (2). But these results fail to clarify whether DHR exercise training that had the effect on DHRIMD. The conclusion also makes no inference to the long-term effects of DHR training. The primary aim of this study was to explore the extent of MD from one bout of 30-min 70%VO2max for 8 weeks (one bout per week) of DHR exercise training. We aim to investigate the reduction of MD.
METHODS: 16 healthy male adults were randomly assigned into 0° (control) and -9° groups based on their pre-determined VO2max. The subjects in the 0°and -9° groups were performed a 30-min DHR (bout1) at gradients of 0° and -9°, respectively, at the intensity of their pre-determined 70%VO2max one bout per week for 8 weeks training. After two weeks of bout1, all the subjects were performed another bout of 30-min, equally-VO2max (70%) DHR (-9°) (bout2). Maximal voluntary isokinetic concentric strength (ISO, 60°/s), upper thigh circumference (CIR), delay onset muscle soreness (DOMS), plasma creatine kinase (CK) were measured before bout1, and before, immediately after, 1, 2, 3, 4 and 5 days after bout2. All data were analyzed by two-way repeated mixed-designed measures ANOVA.
RESULTS: All variables before bout1 and bout2, no significant differences were evident between the groups ($P > 0.05$). The changes in all variables after bout2 were smaller ($P < 0.05$) for the -9° group than for the 0° group.
CONCLUSION: It was concluded that eight weeks of DHR training (-9° DHR) produces better protective effect than level running training.

RISK LIKELIHOOD AND THE METABOLIC IMPACT OF LOW ENERGY AVAILABILITY: A PILOT STUDY

ALLEN, R., SHAW, C., HOFFMANN, S.

DEAKIN UNIVERSITY

INTRODUCTION:Low energy availability (LEA) is an imbalance between energy intake and exercise energy expenditure, resulting in insufficient energy to support bodily functions necessary for optimal health and performance. The potentially negative effects of being in a state of chronic LEA are nutrient deficiencies, impaired immune function and bone health, and reduced sports performance (1). Although resting metabolic rate is reportedly lower in those with LEA (2), little is known about the impact of LEA on metabolic function during exercise. The aim of this pilot study was to determine if exercise economy, substrate utilisation or lactate threshold differed based on LEA risk likelihood.
METHODS: Eight recreationally-active females [mean ± SD: age, 28 ± 5 years; maximal oxygen uptake (VO2max), 41.84 ± 4.99 mL·kg 1·min 1] completed the Low Energy Availability in Females Questionnaire (LEAF-Q) to determine their 'likelihood of being at risk' of LEA. Participants completed two separate exercise trials on a treadmill; an incremental test to determine substrate utilisation (rate of maximal fat oxidation (MFO); and a two-phase incremental exercise test for the determination of exercise economy, the second lactate threshold (LT2) and VO2max. Exercise trials were timed in relation to ovarian hormone concentrations to minimise their potential influence on the outcome variables. Due to the small sample size, interpretative visual analysis of the data was undertaken.
RESULTS: LEAF-Q results classified seven participants as 'unlikely to be at risk' and one participant as 'likely to be at risk' of LEA. In comparison to those classified as 'unlikely to be at risk', the participant 'likely to be at risk' reported a higher weekly training time, and possessed a higher VO2max, LT2 and MFO. In contrast, those 'unlikely to be at risk' were superior in running economy.
CONCLUSION: This pilot study was the first to investigate the impact of LEA risk on metabolic outcomes related to running performance in recreationally-active females. The finding that those who are 'likely to be at risk' of LEA may have a superior VO2max, LT2 and MFO but reduced running economy compared to those whose risk is 'unlikely' suggests that LEA risk likelihood may only have a small influence on running performance. Consequently, being at risk of LEA may be missed as a potential risk factor for longer-term health deficiencies and poor sports performance. Although the higher weekly training time reported by the participant 'likely to be at risk' of LEA may explain the higher VO2max, LT2 and MFO, the reduced running economy compared to those 'unlikely' to be at risk requires further investigation. These pilot results suggest that a larger research study is warranted into the metabolic impact of LEA, with a specific focus on females involved in endurance training and competitions.

HIGHER SKIN-GAS ACETONE CONCENTRATIONS ON SURFACE OF REPEATED KNEE-EXTENSION EXERCISED LEG MUSCLES COMPARED TO OPPOSITE NON-EXERCISED LEG MUSCLES.

KATO, A., KATO, H., UTSU, U., MINAGAWA, A., TAJIRI, N., TSUDA, T., ITOH, H.

NAGOYA INSITITUTE OF TECHNOLOGY

INTRODUCTION:Ketone bodies (3-hydroxybutyrate, acetoacetate and acetone) are generated in the liver, mainly from the oxidation of fatty acids, and exported to other tissues for use as energy source during exercise (1). Therefore, it is known that exercise increases acetone levels in plasma (2), expired air and skin-gas (3). On the other hand, no one has demonstrated changes in skin-gas acetone concentrations directly collected from surface of active muscles following short-term repeated exercise. The purpose of this study was to investigate the difference in skin-gas acetone concentration between repeated knee-extension exercised leg muscles and opposite non-exercised leg muscles.
METHODS: Twelve healthy male students (20.5 ± 0.8 years; mean ± SD) performed 3 sets of 2-min repeated knee-extension exercise (10%1RM, time/2s) with 3-min rest during each exercise bout. The skin-gas samples were collected from exercised quadriceps muscle surface (right leg; R) and opposite non-exercised muscle surface (left leg; L) by covering with a polyethylene bag in which pure nitrogen gas (150mL) was introduced for 30 sec, and collected in a sampling bag at rest, 5, 10, 15 min during exercise bout, and 5, 10, 20 min recovery of the exercise. Acetone concentration was analyzed by gas chromatography. Blood flow was measured with a noncontact-type laser-Doppler flowmetry (LDF) probe.

RESULTS: Skin-gas acetone concentration significantly increased in R during the exercise bout compared to the resting values ($p<0.001$), then immediately returned to the resting levels. On the other hand, no significant change in skin-gas acetone concentration was found in L during and after the exercise. There was a significant relationship between blood flow and skin-gas acetone concentration ($r=0.431$, $p<0.05$) in R.
CONCLUSION: Increased skin-gas acetone concentrations in exercised leg have suggested that repeated knee-extension exercise in this study induced the production of ketone bodies in the liver, from the oxidation of fatty acids (1), and some of increased ketone bodies eliminated as skin-gas acetone. Therefore, skin-gas acetone concentrations related blood flow changes in muscle tissues. Thus, we observed higher skin-gas acetone concentrations on surface of exercised muscles compared to opposite non-exercised muscles following repeated knee-extension exercise.

A TWO-DAY WET-BULB GLOBE TEMPERATURE PREDICTION MODEL TO PROTECT STUDENTS IN SCHOOL GYMNASIUMS

TAKAHASHI, K.1, OHGANE, A.1, INASHIMA, S.2, KIM, H.Y.3

1: KINJO GAKUIN UNIVERSITY, 2: AICHI PREFECTURAL UNIVERSITY, 3: NANZAN UNIVERSITY

Introduction
Because of global warming, preventing heat exhaustion is a critical issue in Japanese schools, where air conditioners are continuously installed in classrooms. In contrast, in gymnasiums, where physical activities are held in elementary school and junior high school, the air conditioner installation rate is only 1.2% (1). Thus, it is necessary to observe temperature, humidity and wet-bulb globe temperature (WBGT) to prevent heatstroke during physical activity in hot environments. Using this data, teachers and coaches can decide whether students can exercise safely. Furthermore, predicting future WBGT is necessary to decide whether exercise can be continued. This study's purpose was to construct a predictive model of future WBGT to protect students in school gymnasiums.
Methods
We measured temperature, humidity and WBGT as per the Ministry of the Environment's method (2), on the second floor of a gymnasium in Nagoya, Japan. The observation period was 15 April to 8 October 2018. WBGT was calculated every hour from globe temperature and wet-bulb temperature through the Data logger heatstroke index meter. We constructed a SARIMA model, a model that considers the seasonal variation effect by applying the Box-Jenkins methodology of classical time series analysis, to predict WBGT. The SARIMA model can be written as follows.
SARIMA (p, d, q) (P, D, Q) (s)
(p, d, q) (P, D, Q) conforming to the model was identified by Akaike's information criterion standard (AIC). Stationarity was determined using an augmented Dickey-Fuller test (ADF). Measured data were classified into training data and test data. Root mean square error (RMSE) was used to evaluate the measured values after modelling.
Results
The RMSE for the prediction model training data was 0.36803; the RMSE for the test data was 0.97893. The actual value fell within the 95% confidence interval of the test data's prediction model. At this time, the parameter (p, d, q) (P, D, Q) was (3, 1, 2) (1, 1, 1), and the AIC was -1104.2. The result of the ADF test on the one-time differential data of the current series was $p < 0.001$.
Conclusion
Our model can predict WBGT two days in advance with accuracy that falls within the 95% confidence interval. This can serve as the basis for constructing more reliable models and can also be used for machine learning. It is necessary to further verify the prediction accuracy of the model using sequential prediction.

EFFECTS OF CORE EXERCISE TRAINING ON LEG BLOOD FLOW AND VASCULAR FUNCTION IN HEALTHY OLDER ADULTS

LIN, H.

NATIONAL TAIWAN UNIVERSITY

INTRODUCTION:Aging is characterized by a loss of muscle mass and blood flow reduction on lower limbs. On the other hand, for older adults, the importance of trunk strength has been recognized on maintaining balance, functional performance and fall prevention. Standing core exercise focused on trunk rotation is suitable for older adults, especially for those with knee concerns. We previously demonstrated a single bout of standing core rotational exercise counteracting to resistance could increase femoral blood flow 60 min after exercise in young, but not older adults. However, its chronic training effects was yet to be determined.
METHODS: Twenty-four healthy middle-aged (69±2 yrs) adults were recruited and randomly assigned to participate either core rotational exercise (C) (75rpm×30mins/each time, 3 times/week) or aerobic walking training (W) (60%-70%HRmax×30mins,) for 8 weeks. Another 12 healthy age-matched (72±4 yrs) healthy controls (CON) were also recruited. Brachial blood pressure, VO2max (Balke protocol), basal femoral hemodynamic measures obtained by ultrasound imaging and arterial tonometry, brachial-ankle pulse wave velocity (baPWV), carotid-femoral pulse wave velocity (cfPWV), and lipid profile were measured before and after the intervention. Physical activity log and food intake analysis were also performed to ensure the treatment effects.
RESULTS: There was no significant group difference in brachial blood pressure, VO2max, PWV, femoral blood flow, as well as lipid profile before training. There was also no between- and within- group difference on physical activity level and food intake. VO2max and baPWV were significantly improved after training only in W group. Femoral blood flow in W and C group was significantly increased after training. Yet, femoral arterial compliance was only improved in W group after training and it was significantly higher than that of CON. Moreover, femoral β-stiffness in W group after training was also lower than that of CON. No significance was observed on femoral compliance and β-stiffness before and after training in the C group.

CONCLUSION: A short-term core exercise training focused on trunk rotation in older adults did not improve vascular function despite femoral blood flow increased. Walking appeared to be an effective and preferable exercise modality to improve lower limb blood flow and vascular function for older adults.

TREADMILL RUNNING IMPROVES PREFRONTAL CORTEX FUNCTION IN LACTATIONAL PHTHALATE-EXPOSED MALE RATS

WU, S.R., WANG, D.C., LEE, Y.C.

KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION:Exercise can improvethe performance of attention task, which is related to brain-derived neurotrophic factor (BDNF) secretion (1). Meanwhile, early life exposure to di-(2-ethylhexyl)-phthalate (DEHP), a plasticizer usually applied in polyvinyl chloride manufacture, may impair regional cortical maturation resulting in attention deficit hyperactivity disorder (ADHD) symptoms of childhood (2). In this study, we investigated the effects of treadmill running on the expression of BDNF and prefrontal cortex function in juvenile male rats that were exposed to DEHP during their lactational period.
METHODS: Rat dams were fed with vehicle or DEHP (10 mg/kg per day) during lactation (postnatal day 2-21). After weaning, the male offspring were divided into 4 groups: control (C, n=9), DEHP (D, n=9), exercised control (Cex, n=8), and exercised DEHP (Dex, n=10). Rats were trained to exercise on a treadmill for 10 weeks from the ages of 4 weeks to 14 weeks and then the prefrontal cortex function was examined by delayed non-match-to-sample task. The activity-related cytoskeleton-associated protein (Arc), a biomarker of neuronal activity, was measured by western blotting. Plasma levels of BDNF were measured by enzyme-linked immunosorbent assay (ELISA).
RESULTS: The results demonstrate that D group exhibited impairedperformance of delayed non-match-to-sample task ($p<0.01$). Decreased expression of Arc protein was observed in the prefrontal cortex of D group rats ($p<0.05$), indicating impaired neuronal activities during delayed non-match-to-sample task. Plasma BDNF level was lower in D group rats ($p<0.05$).Importantly, in the Dex animals, treadmill running recovered the performance of delayed non-match-to-sample task and expression of Arc protein by normalizing the plasma BDNF secretion.
CONCLUSION: Early-life exercise can enhance capacity to evoke BDNF secretion and to reduce the risk of neurodegenerationcaused by lactational environmental phthalate exposure. The findings of this study suggest that treadmill running may provide beneficial effects on ameliorating the dysfunction of prefrontal cortex in the lactational DEHP-exposed male rats at their young age.

SHORT-TERM EFFECTS OF INTERMITTENT HYPOBARIC HYPOXIA EXPOSURE ON MUSCLE INJURY RECOVERY

TORRELLA, J.R., SANTOCILDES, G., ESPITIA-PORRAS, L.F., MILLÁN, L.I., RIZO-ROCA, D., PAGÈS, T., VISCOR, G.

UNIVERSITAT DE BARCELONA

INTRODUCTION:Intermittent hypobaric hypoxia (IHH) has been proposed for several types of non-pharmacological treatments such as therapy for cardiovascular diseases (1) and muscle injury recovery. A 2-week exposure to IHH has demonstrated to improve muscle morphofunctionality, microvasculature and an upregulation of mitochondrial biogenesis and dynamics markers (2,3). Our investigation aimed to explore the short-term effects of IHH on the process of muscle repair from a histological and functional point of view.
METHODS: After surgical injury of the rat gastrocnemius, animals were assigned to two groups (n=7): HYPO, submitted to a protocol of IHH exposure (4h/day, 9 days, 4,500 m); and CTRL, maintained at normoxic conditions. Two muscle zones (intermediate and white) from the gastrocnemius muscle were analysed for fibre type proportion, muscle capillary density, fibre capillarization and fibre cross-sectional area after histological slides stained for succinate dehydrogenase and m-ATPase. Haematoxylin-Eosin (HE) staining was used to assess the extent of histological muscle injury recovery. Force properties of both contralateral injured and healthy muscle were registered by electrical stimulation of sciatic nerve. Peak (PF in mN/g) and tetanic force (TF in mN/g), contraction time (CT), and low frequency (30 Hz) fatigue parameters were measured.
RESULTS: After 9 days, injured leg from the CTRL group registered significant lower values than the healthy leg in PF (50±4 vs 57±4, $p=0.012$), TF (193±17 vs 222±17, $p=0.034$), and showed lower resistance to fatigue. On the contrary, IHH group evidenced a complete functional restoration in force performance of the injured leg (PF: 60±8, TF: 222±23) as compared to its contralateral healthy leg (PF: 59±8, TF: 211±22), and in resistance to fatigue at low frequency. HE staining showed a reduction in the extent of total injury in HYPO (15%) as compared to CTRL animals (23%). However, no significant changes were registered neither in fibre morphometry nor global muscle or individual fibre capillarization. Fibre type proportions remained also unchanged after the IHH protocol.
CONCLUSION: A short-term IHH protocol reduced histological muscle injury and recovered force generation parameters and resistance to fatigue, which were altered in injured muscle. Since the short time exposure to IHH was not enough to elicit fibre morphometry nor capillarization changes in the non-injured muscle areas, the observed functional improvement could be due to accelerated muscle regeneration of the injured region. We hypothesize that IHH could trigger signalling pathways implying the release of growth factors favouring muscle regeneration, thus accelerating muscle repair and restoring functional force performance.

THE INFLUENCE OF INTAKE THE DIFFERENCES DRINKS ON URINARY ELECTROLYTE IN THE SPECTATORS UNDER A HOT ENVIRONMENT

IIDA, T.1, SEKI, K.2, TAKAGI, Y.3, NISHIMURA, K.4, MIYASAKA, Y.5

1: SHUJITSU UNIVERSITY, 2: UNIVERSITY OF MARKETING AND DISTRIBUTION SCIENCES, 3:NARA UNIVERSITY OF EDUCATION, 4: HIROSHIMA INSTITUTE OF TECHNOLOGY, 5: SHOBI UNIVERSITY

INTRODUCTION:The high school baseball game is one of the most popular sport games in summer, Japan. Recently, spectators of sport games may develop the risk of heat disorders as well as athletes. However, there are few reports in thermophysiological response of the spectators. Our previous reports suggest that the intake of only barely tea is not enough electorolyte in summer. Therefore, the aim of this study was to investigate the influence of intake the difference drinks on the condition changes in the spectators of high school baseball.
METHODS: Fourteen healthy Japanese young men volunteered to this investigation. The subjects watched the high school baseball game for two hours under a hot environment. We set the two groups; intake the barley tea group (n=7. Age: 21 ± 1 years, weight: 63.5 ± 10.7 kg,

height: 174.8 ± 8.9 cm, BMI: 20.8 ± 3.2) and intake the sports drink group (n=7. Age: 22 ± 3 years, weight: 56.8 ± 7.4 kg, height: 166.8 ± 2.6 cm, BMI: 20.4 ± 2.7). The measurement were atomospheric temperature, relative humidity, WBGT (Wet-Bulb Glove Temperature), volume of the intake, body weight, thermal sensation, thirsty sensation, pulse rate, urine volume and urinary electrolyte concentration.
RESULTS: Atomospheric temperature: 33.2 ± 1.3 ℃, relative humidity: 44.2 ± 5.8 % and WBGT: 29.1 ± 1.1 ℃ indicated strict vigilance (intense exercise cancel) from the guideline prevention for heat disorders by JSPO (Japan Sports Assosiation). The volume of intake indicated 548 ± 149 ml: barley tea group and 556 ± 186 ml: sports drink group. The dehydration rate of barley tea group was 0.20 ± 0.25 % and that of sports drink group was 0.29 ± 0.38 %. No significant differences were found on the dehydration rate between the two groups. Urinary Na / Cr (0.87 ± 0.41) and urinary Cl / Cr (1.06 ± 0.47) after the game siginificantly lowere than that of the before game (Na / Cr: 1.27 ± 0.50, Cl / Cr: 1.44 ± 0.47) in both groups ($p<0.05$). However, no significant differences were found on urinary Na・Cl observed between the two groups.
CONCLUSION: These results indicate that there are not significant difference on the dehydration rate and urinary electrolyte between the intake of the barley tea and the sports dorink. However, we will speculate that the differences of the two drinks inciate urinary electrolyte in association with increase of dehydration rate if the time of watch are longer than that of this investigation.

TREADMILL RUNNING IMPROVES SYMPTOMS OF POSTPARTUM DEPRESSION IN LACTATIONAL PHTHALATE-EXPOSED FEMALE RATS

TU, T.W., LEE, Y.J., WANG, D.C., LEE, Y.C.
KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION:The incidence of depression is high during the perinatal period. This mood disorder can have a significant impact on the mother, the child and the family. Brain-derived neurotrophic factor (BDNF) plays a key role in the pathophysiology and treatment of depression, which can be induced by exercise (1). Exercise performed during pregnancy may reduce the prevalence of depression in late pregnancy and postpartum (2). Meanwhile, exposure of di-(2-ethylhexyl)-phthalate (DEHP), a plasticizer usually applied in polyvinyl chloride manufacture, is associated with depressive symptoms, particularly the affective and spiritual symptoms (3). In this study, we investigated the effects of treadmill running on the expression of BDNF and symptoms of postpartum depression in lactational DEHP-exposed female rats.
METHODS: Rat dams were fed with vehicle or DEHP (10 mg/kg per day) during lactation (postnatal day 2-21). After weaning, the female offspring were divided into 4 groups: control (C, n=8), DEHP (D, n=8), exercised control (Cex, n=8), and exercised DEHP (Dex, n=8). Rats were trained to exercise on a treadmill for 10 weeks from the age of 4 weeks to 14 weeks. On the age of 14 weeks, female rats were mated to breed their offspring. On the postpartum day 8, dams were subjected to elevated plus maze and open field activity to evaluate the stress responses. Rats were sacrificed 30 min after behavioral tests. Plasma levels of BDNF, adrenocorticotropic hormone (ACTH), and corticosterone were measured by enzyme-linked immunosorbent assay (ELISA).
RESULTS: The results demonstrate that D group exhibited less open arm exploration time in elevated plus maze ($p<0.05$), indicating increased anxiety-like behavior in D group. Increased plasma ACTH level ($p<0.05$), but not corticosterone level, was observed in D group. Plasma BDNF level was lower in D group ($p<0.05$). Importantly, there was no significant difference between C and Dex in anxiety-like behavior, ACTH, corticosterone, and BDNF levels.
CONCLUSION: Early-life exercise can enhance capacity to evoke BDNF secretion and to reduce the risk of symptoms of postpartum depression caused by environmental phthalate exposure. The findings of this study suggest that treadmill running may provide beneficial effects on ameliorating the dysregulation of stress response in lactational DEHP-exposed female rats on the postpartum period.

HYPERFUNCTION OF VO_2 BY EXPOSURING PERIODIC HYPOBARIC NORMOXIA DURING RECOVERY PERIOD AFTER ONE MINUTE SUPRAMAXIMAL EXERCISE BOUT

FUJITO, Y.1, NOZAWA, T.2, KIUCHI, A.2, ABE, N.2, KASHIWAGI, Y.3, KAWAKAMI, Y.U.4, MASHIKO, K.5, KAWAKAMI, Y.O.4, FUNATO, K.1
1: NIPPON SPORT SCIENCE UNIVERSITY.,2: GRADUATE SCHOOL OF HEALTH AND SPORT SCIENCE,NIPPON SPORT SCIENCE UNIVERSITY.,3: SENSHU UNIVERSITY.,4: SHINMEI-ROOM INC.,5: KYOWA KENSHO INC.

INTRODUCTION:A recovery after training and severe important period as to return metabolism to normal. As there are many methods to promote a recovery, athletes can promote a recovery by exposuring the atmospheric pressure. The Periodic Hypobaric Normoxia Environment (PHNC) have newly developed recently, where improvement of ventilation efficiency and the promotion of fat metabolism were reported in resting condition [1, 2]. However there is no study reported of an exercise in sea level and rest in PHNC. Purpose of this study was to investigate on a physiological response such as PHNC on oxygen uptake (VO_2), HR and blood lactic acid (La) during recovery period after supramaximal exercise.
METHODS: Four healthy male athletes (21.5±0.5 yrs, 173.2±5.1cm, 71.5±6.8kg) participated in this study. All tests were conducted by an electromagnetically braked cycle ergometer, and PHNC was an environment that repeats cycles of decompression (Atmospheric pressure: approximately 670mmHg) in 3 minutes and abdominal pressure (Atmospheric pressure: approximately 730mmHg) in 3 minutes. At first, subjects had been measured the maximal oxygen uptake(VO_2max). Secondly, supramaximal constant exercise are performed at 115%VO_2max of 1min, and the rest after two different conditions of 60min recovery (NN vs. PHNC).
RESULTS: During the exercise, there was no significantly difference in VO_2 in two conditions. VE, HR and La no differences in two conditions during recovery period. On the other hand in PHNC condition, VO_2 and a time constant were higher, and VE/VO_2 and R were lower compared to NN condition. Improvement of ventilation efficiency and promotion of a fat metabolism might be suggested by staying at PHNC. PHNC exposure had no influence on blood lactic acid accumulations.
CONCLUSION: Hyperfunctions of VO_2 and fat metabolism might be suggested by exposuring PHNC during recovery period after one minute supramaximal exercise bout.

STRENGTH, POWER AND MUSCULAR STIFFNESS DETERMINANTS OF STROKE VELOCITY IN COMPETITIVE YOUNG TENNIS PLAYERS

COLOMAR, J., BAIGET, E., CORBI, F.

INEFC-BARCELONA

INTRODUCTION:It's commonly been accepted that tennis strokes, especially the tennis serve, are influenced by several parameters such as technique, anthropometrics, strength and power values and range of movement characteristics, making the action of a multi-factorial nature (1,2). Nevertheless, the relationship between stroke velocity (StV), strength and power characteristics, muscular stiffness values and the player's level remains unclear, especially regarding young tennis players and the groundstroke actions. For this reason, the aims of this study were (a) to examine the relationship between strength and power characteristics, individual muscle stiffness values, competitive level and StV in competitive young tennis players, and (b) to determine a prediction model based on the relationship between these variables.
METHODS: Twenty-one competitive male tennis players (mean ± SD; age, 17.0 ± 0.8 years; height, 180.0 ± 10.0 cm; weight, 72.3 ± 5.8 kg; BMI 22.1 ± 1.5) with an International Tennis Number (ITN) ranging from 2 to 4 participated in this study. Subjects performed individual muscle stiffness, stroke velocity (serve, forehand and backhand velocity [SV, FV and BV]), strength (maximum dynamic and isometric strength) and power (medicine ball throws (MBT), squat jump (SJ), countermovement jump (CMJ), peak bench press power (Wmax) measurements. Bivariate and multivariate models for predicting StV were developed.
RESULTS: Moderate inverse correlations were found between SV and ITN (r = -0.43), and large positive correlations were observed between pectoralis majoris stiffness [PStiff] (r = 0.53), isometric wrist flexion [IsoWrF] (r = 0.58) and ITN respectively. Also, PStiff was moderately inversely correlated to FV (r = -0.45) and gastrocnemius stiffness [GStiff] to SV (r = -0.45). ITN, infraspinatus [IStiff] and pectoralis majoris stiffness [PMStiff] explained 34% and 21% of variability in SV and FV respectively.
CONCLUSION: The results of this study highlight the fact that strength and power characteristics seem to be poor predictors of stroke velocity for young tennis players. Certain individual muscle stiffness values together with ITN could somehow be predictors of StV and should be taken into account when training to enhance velocity production in young tennis player.

2)Palmer, K, Jones, D, Morgan, C, Zeppieri, G. Relationship between range of motion, strength, motor control, power, and the tennis serve in competitive-level tennis players: A pilot study. Sports Health 10(5):462–7, 2018.

SEASONAL CHANGES IN MAXIMAL AND SUB-MAXIMAL AEROBIC VARIABLES TO PREDICT CYCLING PERFORMANCE

POPRZECKI, S., PLOSZCZYCA, K., MIKOLAJEC, K., STANULA, A., MASZCZYK, A., ZEBROWSKA, A.

ACADEMY OF PHYSICAL EDUCATION

INTRODUCTION:Road cycling is a sport activities in which aerobic metabolism plays a key role. VO2max, WRmax, lactate threshold (LT), HR, LA,VE were measured over seasonal cyclists training for a monitoring and predicted of training performance. Tests for submaximal, steady state, and maximum intensity were most often used to control and predict the ability to exercise during the cycling preparation season (1,2). The aim of this study was to compare seasonal changes in physiological parameters over exhaustive test at LT and maximum stage.
METHODS: Nine road cyclists volunteered for this study, aged (25,6±5,2 years), weight (72,41±7,35 kg). In each of the four periods, a exhaustive test was performed. Periods: transition (T0- baseline data), preparatory (T1), peak of preparatory (T2), and competition (T3). VO2max test was performed at the cycle-ergometer LODE Excalibur Sport. After maximum and submaximal stage (LT) of the test the physiological parameters were measured. All variables were calculated using a one way analysis of variance (ANOVA), multiple regression and Pearson correlation. The level of significance for all analyses was set at $p<0,05$.
RESULTS: After the maximum test stage a significant main effect for training was found for: absolute-p=0,016 and relative – p=0,028 WRmax, VO2max/WRmax (p=0,023), Ve max (p=0,005), TTmax (p=0,020). Not significantly differentiated VO2max, HRmax, WRmax/VO2max. During submaximal stage (LT threshold), training significantly differentiated: VO2LT (absolute-p=0,000, relative-p=0,000), WRLT (absolute-p=0,000, relative-p=0,000), %VO2max at LT (p=0,005), HRLT (p=0,012) and no significant main effect was found in: TTLT and WRLT/VO2LT. Correlation for standardized data between maximal vs. submaximal intensity in VO2max test: T0 – r=0,87, (p=0,002), T1-r=0,73, (p=0,027), T2-r=0,60 (NS), T3-r=0,76 (p=0,017).: Significant effect predictors of the dependent variable VO2max for these study Test 0 (T0)- VO2max/HRmax (p=0,001), HRmax (p=0,025), T1 -VO2max/HRmax (p=0,002), HRmax (p=0,017), T2-WRmax/VO2max (p=0,042), VO2max/HRmax (p=0,020), HRmax (p=0,029), T3- WRmaxRV (p=0,019), %VO2max at LT (p=0,044).
CONCLUSION: The present study showed the reliability of maximal and submaximal physiological variables used to assess cyclists performances. Submaximal variables seem to be the best to monitor changes in training status over a season. The reliability of the VO2max test performance, was be designed to accurately predict and seasonal monitor the cyclists performance. Predictors of the dependent variable VO2max, taking into account individual test measurements. Significant effect was set: WRmaxRV, VO2max/HRmax, WRmax/VO2max, HRmax, VO2LT and %VO2max at LT.

RELATIONSHIP BETWEEN PHYSICAL ACTIVITY, SLEEP, AND CAROTID ARTERY HEALTH IN OLDER ADULTS.

PARK, H.

DONG-A UNIVERSITY

INTRODUCTION:Physical activity has long been associated with better sleep, and physical activity and sleep are closely related behaviors with suggested synergistic influence on cardiovascular and coronary artery health. The aim of this study was to examine the relationship between physical activity and sleep pattern, and carotid artery atherosclerosis in older population.
METHODS: A total of 214 participants (age range, 65-87 years) were recruited. Carotid artery arteriosclerosis was evaluated B-mode ultrasound and quantified as intima-medial thickness (IMT). The risk of carotid artery atherosclerosis was defined as IMT≥1.2 mm. Physical activity was objectively measured using 3 axial accelerometer and sleep was measured by PSQI. Analyses included multivariate logistic regression models with physical activity and sleep duration and quality as main predictors of the estimated risk of the carotid artery atherosclerosis after controlling for confounding factors such as age, sex, blood pressure, alcohol intake, and smoking habit.

RESULTS: The interaction between MVPA and sleep duration was significant, with higher risk of carotid artery atherosclerosis. Low-dose of moderate-to-vigorous physical activity (<15min/day) and longer sleep duration >7.2 h correlated significantly with the risk of carotid artery atherosclerosis when compared with a high does group (>15min/day) and a sleep duration of 6 h (multivariate-adjusted odds ratio, 2.1 and 1.7 respectively).
CONCLUSION: Our findings suggest that MVPA modifies the association particularly between sleep disturbance and the risk of atherosclerosis where the coexistence of long sleep and insufficient MVPA contribute significantly to the excess atherosclerosis risk. Poor sleep associates with impaired glucose metabolism and obesity, low inflammation, and hypertension, all that make up possible mechanisms for the relationship between long sleep and the risk of atherosclerosis. Moreover, physical activity modifies cardiometabolic risk factors, and low physical activity is an established risk factor for CVD risk.

THE ASSOCIATION BETWEEN PHYSICAL ACTIVITY AND PRIMARY DYSMENORRHEA IN YOUNG JAPANESE WOMEN

USUI, C.1, MITA, Y.2

1 WASEDA UNIVERSITY, 2 SUGIYAMA JOGAKUEN UNIVERSITY

INTRODUCTION:Primary dysmenorrhea is cramping lower abdominal pain during menstruation in the absence of underlying pathology and is one of the most common gynecological disorder in young women. It can cause absenteeism and affects quality of life in young women. There are several non–medicinal methods for improving this complication and increasing physical activity has been recommended for primary dysmenorrhea. Some studies have proposed aerobic exercise as effective in the treatment of dysmenorrhea (1), but one study found no relationship between exercise and dysmenorrhea (2). The present study was conducted to investigate the relationship between physical activity and primary dysmenorrhea in young Japanese women.
METHODS: Self–administered questionnaire which included menstrual pattern, dysmenorrhea score, life style and physical activity was used to collect data from 362 female university students aged 18–24 years in Japan. All subjects were divided into three groups according to dysmenorrhea score: score 0 was non–dysmenorrhea group (Non), score 1–2 was mild dysmenorrhea group (Mild), and score over 3 was severe dysmenorrhea group (Severe). One–way ANOVA or Kruskal–Wallis ANOVA analysis were carried out.
RESULTS: The age at menarche in Non group was significantly later than other two groups (Non: 12.9±1.5 vs Mild: 12.3±1.5 vs Severe: 12.2±1.3 years, p = 0.006). Subjects in the Non group had significantly higher vigorous leisure time physical activity compared with Severe group (Non: 28.7±72.9 vs Severe: 11.5±47.1 METs･h/wk, p = 0.021), even though no significant differences in total physical activity among three groups.
CONCLUSION: This study suggested that increasing physical activity, especially vigorous leisure time physical activity, may be an effective treatment for primary dysmenorrhea. We think that educational measures about the effect of proper physical activity on primary dysmenorrhea are required to improve the quality of life among young women.

SUSTAINED EFFECTS OF MULTIPLE CONCUSSIONS ON PREFRONTAL CORTEX OXYGENATION DURING A BAROREFLEX MANOEUVER IN RETIRED CONTACT SPORT ATHLETES

NEARY, J.P.1, SINGH, J.1, SIRANT, L.W.1, GAUL, C.A.2, STUART-HILL, L.2, MARTIN, S.2.

1 UNIVERSITY OF REGINA, 2 UNIVERSITY OF VICTORIA

INTRODUCTION:Concussions have recently gained widespread interest, and as such, there is an increase in the general awareness of the damage they may cause, suggesting possible long lasting symptoms even years after trauma. Recent research has suggested that both autonomic function and cerebral autoregulation can be altered due to concussion (1,2). One way to assess these changes is to observe the baroreflex mechanism, which helps maintain blood pressure at nearly constant levels by inducing changes in the cardiac cycle. What is not known is if changes in autoregulation are more severe over time due to prior concussion as compared to the ageing process. The purpose of this study was to compare changes in cerebral haemodynamics during a squat-stand baroreflex manoeuver between retired contact sport athletes and healthy age-matched controls.
METHODS: 7 healthy, male controls without concussion history (age=66±8 years) and 7 retired contact sport male athletes with confirmed multiple concussions (age=65±8 years), all of whom are physically active, had their right prefrontal cortex haemodynamic activity measured by near infrared spectroscopy (NIRS). NIRS parameters measured included local tissue saturation (%TSI), oxygenated haemoglobin (HbO2), deoxygenated haemoglobin (HHb), total haemoglobin (tHb), and haemoglobin difference (HbDiff) in the prefrontal cortex with the NIRS device placed 1 cm above the eyebrow. Participants were seated and instructed to breathe normally for 5 minutes to establish spontaneous baseline physiology. To assess baroreflex control, participants were instructed to squat down to 90 degrees for 10 seconds and stand up for 10 seconds (0.05Hz; repeated 15 times over 5 minutes). NIRS data during the squat-stand manoeuver was calculated by subtracting from the average 5 minute resting value, thus reflecting a change from baseline.
RESULTS: Independent sample t-tests revealed significant decreases (p=0.04) in HbDiff in participants with prior concussions (1.22±1.52 μM) compared to healthy controls (3.65±2.32 μM), reflecting a decrease of 67%. No statistically significant differences were found in %TSI (p=0.70; 127% decrease), HbO2 (p=0.06; 59% decrease), HHb (p=0.80; 48% increase) or tHb (p=0.30; 52% decrease).
CONCLUSION: These results provide preliminary evidence that cerebral autonomic function, as measured by haemodynamic activity during a baroreflex manoeuver, may be impaired in those athletes with prior multiple sustained concussions. HbDiff = HbO2 - HHb, thereby suggesting that oxygen utilization or metabolism is altered in the prefrontal cortex. Multiple concussions may have long-term effects which hinder oxygen metabolism in ways that differ from age-induced changes. However, a larger sample size is required to provide greater insight into the long-term cerebral haemodynamic changes that may occur due to prior concussions.

RELATIONSHIP OF HEART RATE VARIABILITY AND TESTOSTERONE/CORTISOL RATIO DURING A 9-WEEK EXERCISE INTERVENTION.

DEBLAUW, J.D., CRAWFORD, D.C., HEINRICH, K.M.

KANSAS STATE UNIVERSITY, PITTSBURG STATE UNIVERSITY

INTRODUCTION:The ability to monitor training status is essential to determine acute and chronic stress effects as part of an individualized exercise prescription. Heart rate variability (HRV) and the testosterone to cortisol ratio (TC) have previously been used to monitor training status. Detecting of changes within an individual's HRV or TC can provide insight into prescribing daily exercise intensities. Currently, the relationship between these two monitoring strategies has yet to be determined during an exercise intervention. Our aim was to determine if a negative linear relationship existed between daily resting HRV and pre-exercise TC throughout an exercise intervention of High Intensity Functional Training (HIFT).
METHODS: Eight recreationally active men (n=4, 24.25±1.75 years) and women (n=4, 26±3.6 years) participated in a 9-week HIFT intervention (5 days/week for 60-minutes). HRV readings were obtained upon waking in a supine position via the smart phone application HRV4Training via photoplethysmography (PPG). Additionally, saliva samples were taken pre-exercise on the final training session of each week (9 samples). Saliva samples were analyzed for concentrations of testosterone (T), cortisol (C), and TC via an enzyme-linked immunosorbent assay. HRV and TC data were checked for normality; TC was transformed using the natural log method (lnTC) prior to statistical analysis. Multiple linear regression analysis with backward model selection was performed. Potential outliers were assessed using the Mahalanobis distance metric; with no influential outliers identified.
RESULTS: The model that best fit the data found that HRV and gender accounted for 23% of the variance in pre-exercise lnTC ($F(2,65) = 9.771$; $p < .001$; $R2 = .231$). Within the final model, both HRV (β= -.257, 95%CI = -.440, -.074; t= -2.8; p< 0.007) and gender (β= .523, 95%CI = .188 - .858; t= 3.1; p< 0.003) significantly predicted lnTC.
CONCLUSION: Our data showed that a negative linear relationship exists between resting HRV and pre-exercise lnTC. Specifically, for each one-unit increase in resting HRV we can expect approximately a 26% (95%CI = 7 - 44%) decrease in TC ratio. Coaches can monitor resting HRV as insight to pre-exercise training status. With this insight, exercise intensity can be manipulated to provide the appropriate training stress in order to obtain the desired training outcomes.

HEPATOCYTE GROWTH FACTOR (HGF) LEVEL AFTER 9 WEEKS OF CROSSFIT AND OTHER FORMS OF HIGH INTENSIVE TRAINING IN YOUNG MEN

MURAWSKA-CIALOWICZ, E.1, ZUWALA-JAGIELLO, J.2, WOLANSKI, P.1

1. UNIVERSITY OF PHYSICAL EDUCATION, DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY, WROCLAW 2. MEDICAL UNIVERSITY, DEPARTMENT OF PHARMACEUTICAL BIOCHEMISTRY, WROCLAW

INTRODUCTION:Physical exercise causes damage to muscle fibres, inflammation, and as a consequence satellite cell (SC) activation and proliferation. The genetic material of satellite cells is combined with the material of a damaged fibre, which intensifies protein biosynthesis. It facilitates myocyte regeneration and stimulation of muscle hypertrophy. An increase in the number of satellite cells depends on, among others, age, type of the damaged muscle fibre, type of training or intensity of exercise.
HGF is a growth factor of mesenchymal origin. It activates SC and stimulates their proliferation, motility, cell differentiation and angiogenesis. It acts as an auto-, para- and hemocrine factor. Due to its ability to rebuild the structure of organs, HGF is being studied as a potential medicine for medical conditions which are accompanied by organ damage. HGF can be of systemic origin as it is secreted by various organs (e.g. lungs or the liver), or of muscle origin as it is secreted by fibroblasts in the muscles.
METHODS: The studied group consisted of healthy, young men who participated in a 9-week training program. The subjects were divided into four separate training groups performing different types of exercise (Crossfit, HIIT, HIPT, HIET). Before the start of the training program and after 9 weeks resting HGF levels were measured. Body composition and circumferences of chosen body parts were also measured. Aerobic capacity was measured with the progressive test carried out on a treadmill and Wingate test was used to measure their anaerobic capacity.
RESULTS: We have noticed that the resting values of HGF changed in all groups after 9 weeks training. In all groups the levels of HGF were higher in comparison to the resting value before training (baseline). In Crossfit (HIFT) group HGF levels were higher by 25% in comparison to the baseline, in HIPT group HGF levels increased by 8,7%, in HIIT by 18,7% and in HIET groups by 29,6%.
We also observed the increase of LBM, reduction of FAT (kg and %) and increase of muscle's circumferences in all measured groups as well as the increase of VO2max and muscle's strength and power.
CONCLUSION: Despite extensive research done into HGF and the confirmation of the role it plays in muscle's regeneration and angiogenesis, little is known about changes in HGF levels in athletes in response to different types of exercise. In our research we proved that HGF levels increase after different forms of intensive training. The most significant changes in resting HGF levels were observed after 9 weeks training in the Crossfit and HIET group. It was surprising that the HIPT generated so small changes of HGF levels.
As we know this is the first observation of HGF after training and the futher research should be still done to discuss the results and explain mechanisms of action and secrection of this factor after exercise and training.

Psychology

THE EFFECT OF MODERATE AEROBIC EXERCISE ON COGNITIVE LEARNING DURING A DUAL N-BACK TASK

LIN, M., WANG, C.H.

KAOHSIUNG VETERANS GENERAL HOSPITAL , & PHYSICAL EDUCATION, HEALTH & LEISURE STUDIES, NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION:Cognitive training has enthused considerable interest among the scientific community and the public at large in the past decade. Interestingly, physical exercise has been consistently associated with benefits to a wide range of cognitive functioning, beyond the well-known physiological and health improvements. Accordingly, this study aimed to address the question whether cognitive training can be enhanced by supplementing exercise training.
METHODS: Thirty young adults were randomly assigned to either the experimental group (n = 15) or the control group (n = 15). For the experimental group, participants took part in a 20-day cognitive training combined with acute bouts of moderate aerobic exercise. For the control group, participants received the same cognitive training regimen with a non-exercise condition (i.e., reading). Cognitive training was administered using a dual n-back task.

RESULTS: Analysis of the data showed a strong training effect for both groups (time effect, p <.001), indicating that the cognitive training was effective, with steady performance improvements seen across the training sessions. Crucially, we observed that the exercise intervention induced different trends of learning (group × time interaction, p = .025), with the evidence showing that the exercise group exhibited better task performance relative to the control group during session 9, 10 and 16 (ps < .045).
CONCLUSION: Taken together, this study suggests that physical exercise could enable more robust improvements in cognitive learning. Our findings also have practical implications for educational policies, as they suggest that exercise may be a viable approach to maximize learning efficiency in the classroom.

PSYCHOMETRIC PROPERTIES OF A SPANISH VERSION OF THE SCALE OF SATISFACTION OF BASIC NEEDS IN SPORTS

PINEDA-ESPEJEL, H.A., TREJO, M.

UNIVERSIDAD AUTÓNOMA DE BAJA CALIFORNIA

The aim of this study was to analyze the psychometric properties (factorial validity, internal consistency, validity based on the relationship with other variables -enjoyment and subjective vitality-) of a Spanish version of the Basic Needs Satisfaction in Sport Scale (BNSSS; Ng, Lonsdale & Hodge, 2011) to validate your use in the Mexican context. A set of questionnaires were administered to 271 Mexican athletes with an average age of 12.06 years (SD = 1.83) and participants from different sports. The results of the confirmatory factor analysis supported both the structure of five related factors (i.e. competence satisfaction, relationship satisfaction, volition, perception of choice, and IPLOC): chi-square(160)=259.959 (p < .001); RMSEA=.056; CFI=.980; NNFI=.983; as the structure of three factors of higher order (i.e. competence satisfaction, relationship satisfaction, and autonomy satisfaction –this one latter composed from volition, perception of choice, and IPLOC-): chi-square(149)=3921.177 (p < .001); RMSEA=.080; CFI=.959; NNFI=.952. The latter model after removal of an item. In addition, the reliability of the subscales was acceptable (omega's Mcdonald > .70) except for the volition factor; and the scores derived from the five factors of the instrument provided evidence of criterion validity, for example, through its positive and significant relationship with enjoyment, and vitality subjective. In conclusion, this version in Spanish of the BNSSS is valid and reliable to measure the satisfaction of basic psychological needs, as well as each of the essential qualities of the nature of autonomy perception.
Ng, J. Y., Lonsdale, C. y Hodge, K. (2011). The Basic Needs Satisfaction in Sport Scale (BNSSS): instrument development and initial validity evidence. Psychology of Sport and Exercise, 12, 257-264.

THE ASSOCIATIONS OF OBJECTIVELY MEASURED PHYSICAL ACTIVITY AND SEDENTARY TIME WITH COGNITIVE FUNCTIONS IN CHILDREN WITH AUTISM

PAN, C.Y., JIANG, S.Y., CHEN, P.L., HUANG, C.Y., TSAI, C.L., CHU, C.H.

NATIONAL KAOHSIUNG NORMAL UNIVERSITY

Introduction
Children with autism might be at particular risk for inactivity due to social and behavioral impairments associated with the condition (Pan & Frey, 2006). Low levels of physical activity (PA) and excessive sedentary behavior may contribute to harmful health outcomes and also on children's cognitive prerequisites of learning (Hillman, Kamijo, Scudder, 2011). To our knowledge, no previous studies have examined the associations of objectively measured PA and sedentary time on cognitive functions in children with autism.
Methods
Twenty-six children with autism, aged 7-13, participated. The ActiGraph GT1M/GT3X accelerometers with vertical axel were used to measure children's moderate to vigorous PA (MVPA) and sedentary time. Children with autism wore an accelerometer on the right hip with an elastic waistband during waking hours for 7 consecutive days except bathing, swimming, and other water activities. Cognitive functions were assessed using the Stroop Color and Word Test and the Wisconsin Card Sorting Task (WCST). Pearson product-moment correlation coefficients were computed to assess the relationships between MVPA, sedentary time, and cognitive tests. The probability level was set at p < .05.
Results
Findings of bivariate correlations indicate that (a) the WCST total correct (r = 0.71, p < .01), conceptual-level response (r = 0.69, p < .01), and categories complete (r = 0.43, p < .05) were positively associated with the percentage of time spent in MVPA, (b) the WCST perseverative responses (r = -0.52, p < .01) and perseverative errors (r = -0.50, p < .01) were negatively associated with the percentage of time spent in MVPA, (c) the WCST total correct (r = -0.43, p < .05), conceptual-level response (r = -0.47, p < .05), and categories complete (r = -0.41, p < .05) were negatively associated with the percentage of time spent in sedentary behavior, and (d) the Stroop index was not correlated with the percentage of time spent in MVPA nor sedentary time.
Discussion
The results of the present study propose that PA may benefit flexibility of children with autism, and excessive sedentary time may have unfavorable influence on cognitive functions. Future studies should assess what kind of PA or sedentary behavior affects specific kinds of cognition, as well as the mechanisms behind these associations.

PHYSICAL PERFORMANCE AND MOTIVATIONAL FACTORS EXAMINATION OF THE 1 ST DIVISION WATERPOLO TEAM

TÓTH, E., NAGYVARADI, K., BIRÓNÉ ILICS, K., POLGÁR, T., LAKI, A., IHÁSZ, F.

EÖTVÖS LONÁND UNIVERSTY

INTRODUCTION:Sports science talent development research explores the mechanisms that assist individuals during the process of becoming elite athletes. Due to the dynamism of sports settings, multidisciplinary perspectives emphasize the combination of physical and

psychological factors as an important aspect of talent development. This study investigated a number of motivational factors, enjoyment, and perceived physical competence perceptions of the 1st division Water polo Team in Hungary.
METHODS: The study was approved by the Research Ethics Committee of ELTE University. We used the "Inbody 720" to measure the body composition of the examined athletes. The cardiorespiratory fitness was measured type H/P Cosmos LE200CE (DE 83365 Nussdorf-Traunstein Germany) by to maximal fatigue. The resting heart rate (beat·min-1 HRrest) and maximal heart rate (HRmax), were measured by "Cardiosoft", (Milwaukee, USA), aerobic capacity (VO2max), ventilation (VE) (BTPS L x min–1) and its components were measured by Master Screen CPX 50/60 Hz type (CareFusion Germany 234 GmbH 97204 Hoechberg) Statistical analysis was performed by Stat. Soft. 2013. Before, during, and after the load, we followed the changes in the pulse with the Polar H7 Bluetooth 4.0 Smart Chest Transmitter. To learn about the motivational basis of athletes, the Sport Motivation Scale (Pelletier et al., 1995), Tsang et al., 2005), the H-SMS questionnaire (Paic et al., 2017) and the Perceived Motivation Climate in Sport Questionnaire-2 (Newton et al., 2000) hungarian adaptation was used (Révész et al., 2014).
RESULTS: The data set presented in this study was collected from 1 st division Water polo players in Szombathely. The sample consisted of 13 male water poloers (n = 23); 25 ± 6.2 years, with an average sports age of 15.92 ± 5.81 years). Their height (BH) is 186.25 ± 8.058 cm, body weight (BW) is 86.03 ± 2.780 kg, body fat mass (PBF) is 12.258 ± 4.394%, and their muscle mass (PSMM) is 50.453 ± 2.768%.) This pretest shows that there is a significant connection between the height and amotivation r = -0.758; p <0.05, and some sub-scales of ventilation and aspirations have a significant correlation. There is also a significant relationship between the qualification of water polo and some sub-scales of development.
CONCLUSION: The main goal of the elite athlets is to reach the highest performance and continuous lifting of the mental and physical boundaries. These factors can be the basis for a teams good seasonal role. Athlete performance is influenced by psychological factors such as making mistakes, punishment from judges or feedback from coaches. Creating a higher level of mental endurance requires a potential positive effect on performance.

EFFECTS OF ACUTE EXERCISE MODALITY ON INHIBITION FROM A BEHAVIORAL AND NEUROPHYSIOLOGICAL APPROACH

WANG, C.C.1, WU, T.Y.2, SONG, T.F.3, CHANG, Y.K.1

1: NATIONAL TAIWAN NORMAL UNIVERSITY, 2: NATIONAL TAIWAN UNIVERSITY OF SPORT, 3: NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION:A growing body of study has explored the relationship between acute exercise and cognition and most of the evidence has indicated that there are positive effects of acute exercise on cognition, particularly on executive functions. Some meta-analysis reviews have shown that the largest positive effects of cognitive change are found following aerobic exercise, and yet these findings suggest that these data may underestimate the effect size of other exercise modalities, due to small sample sizes. Recently, some studies have shifted a little attention to resistance exercise, and its positive effects on cognition were also found. However, the purpose of this study was to examine the effects of an acute exercise modality on a Stroop test, as well as on a neurophysiological mechanism.
METHODS: 34 college and Masters level students were recruited and all participants performed conditions of rest, aerobic exercise, and resistance exercise on separate days, in a counterbalanced order. The Stroop test was administrated following each condition in order to assess inhibition responses. The N1 and N2 components of ERP were measured during the Stroop test performance in order to assess the test participants' neuroelectric activity as a neurophysiological mechanism.
RESULTS: There was a shorter response time following the cessation of the acute exercise, compared to the resting condition, across all conditions of the Stroop test, and no differences between acute aerobic and resistance exercise results were found. The accuracy rate was not significantly changed following the three treatments. No effects of acute exercise on N1 and N2 amplitude were observed.
CONCLUSION: Our findings suggest that the improvement of inhibition may be induced by acute aerobic and resistance exercises, and that there were no differences of cognitive change response to either exercise modality. The beneficial effects of cognitive behavior were not impacted by earlier information and/or sensory processes, according to the earlier measured ERP components.

THE HEMISPHERE-SPECIFIC ATTENTIONAL RESOURCE ALLOCATIONS AMONG DIFFERENT BALL SPORT ATHLETES

WU, S.K., CHIANG, C.H., LIEW, Y.W., CHEN, W.Y.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION:The attentional process for tracking moving objects may be mediated by two independent resource pools, one in each cortical hemisphere. Alvarez & Cavanagh (2005) suggested that the attentional resource consumed by additional targets is hemisphere-specific by that the tracking performance for tracking targets in one visual hemifield was not significantly affected by a requirement to track additional targets in the other hemifield. When the additional targets instead occupied the same hemifield as the original targets, the tracking performance was reduced. The specific demands of a ball sport may be reflected in the tracking performance of the hemisphere-specific task. Table tennis (TT) and badminton (BM) athletes play the game with the dominant hand holding a racket, but baseball (BB) players have to swing the bat to hit the ball with two hands. The purpose of the study was to examine whether specific characteristics of ball sports affect the tracking performance of the hemisphere-specific task.
METHODS: We recruited 30 BB players, 15 BM players, 11 TT players and 15 non-athletes as control group were recruited in this study. The hemisphere-specific attentional resource allocations for all participants were measured with the modified task of the Alvarez & Cavanagh (2005)s task. Participants were asked to attentively track 1 or 2 targets in certain quadrant of the computer monitor among some distractors for a few seconds, and participants reported those targets in the end of trial. We manipulated the objects' moving speeds (0.6, 0.9, 1.2 deg/s), the tracked target numbers (1 or 2 targets), and the 2 different visual conditions (same or opposite visual field). Participants ran in 120 trials in a task in two separate periods (competition period and training period) of the specific sports.
RESULTS: A significant group effect was shown according to a Mixed-Model Repeated Measures ANOVA ($F(3,67)= 2.785$, $p<0.001$), post hoc showed that tracking accuracy of TT players was significantly higher than BM players ($p=0.009$) and non-athletes ($p=0.033$). Consistent with the hemisphere-specific resource theory, the tracking accuracy was significantly lower when tracking two targets in the same visual hemifield (left or right) than in the opposite hemifield ($p<0.001$). It was significantly higher for tracking one target across participants than for tracking two targets ($p<0.001$). The tracking accuracy decreased significantly as the speed increasing from 0.6 to 1.2 deg/s. No significant difference between the training and the competition periods was found.
CONCLUSION: The study identified that TT players performed better than non-athletes and BM players in the task, indicating that hemisphere-specific attentional resource allocations might be different according to the specific demands of a ball sport. Future studies could utilize these results to establish a standardized testing procedure for talent identification of athletes in ball sports.

MENTAL HEALTH ASSESSMENT OF JAPANESE FOOTBALL REFEREES

MURAKAMI, K.1., MATSUURA, M.1.

1: TOKYO UNIVERSITY OF SCIENCE

Introduction
Referees must continuously endure physical pressure; as well as various psychological stressors. For example, professional football referees function in a difficult psychosocial environment and are exposed to such physical and psychosocial stressors as energetic and physical load, injuries, social pressure, and media scrutiny (Arnold et al., 2012). Thus, football referees are likely to experience mental health problems. This study aimed to investigate the mental health problems in Japanese football referees, and explore the views of football referees on support and needs related to these problems.
Methods
In collaboration with the Japan Football Association (JFA), we recruited a sample of 52 JFA-certified referees who refereed at the 2018 National League Division 1. The mean age of the 52 participants was 35.8 years and they had refereed in football for 15.9 years on average. The Mental Health Pattern Inventory (MHP; Hashimoto, et al., 1999) was used to assess mental health problems related to persistence, distress, anti-social behaviour, tension towards others, fatigue, sleep disorder, and life satisfaction in the previous four weeks. In addition, three single statements were used to explore the view of the participants on support and needs related to mental health problems.
Results
The incidence of mental health problem symptoms (self-reported and not clinically diagnosed) among JFA-certified referees was 19.2% for persistence, 9.6% for distress, 27.0% for anti-social behaviour, 40.3% for tension towards others, 11.5% for fatigue, and 28.8% for sleeping disorder. More than 80% of the JFA-certified referees thought that mental health problem symptoms can negatively influence their refereeing performance, but only 10% of them had sought professional help for their mental health problems.
Discussion
The incidence of symptoms of mental health problems among JFA-certified referees ranged from 9.6% for distress to 40.3% for tension towards others. Overall, the present investigation revealed that the referees in the present sample experienced similar mental health issues as European professional football referees (Gouttebarge et al., 2017). As mental health problem symptoms can negatively influence refereeing performance, JFA-certified referees reported that specific support measures for them need to be developed to help them manage these mental health problems.

RESISTANCE AND AEROBIC EXERCISE PRODUCE DISTINCT MOLECULAR AND NEUROCOGNITIVE EFFECTS IN PATIENTS WITH MILD COGNITIVE IMPAIRMENT

TSAI, C.

NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION:Reduced neurocognitive functions and metabolic disturbances are associated with mild cognitive impairment (MCI) (1,2). Physical exercise has been demonstrated to be effective on these disadvantageous phenomena (3). However, no studies have yet been conducted on whether regular exercise can effectively facilitate neurocognitive performance and improve the levels of metabolic biomarkers in individuals with MCI. Therefore, the present study was aimed to explore the effects of resistance and aerobic exercise interventions on insulin/leptin and behavior/event-related potential (ERP) in patients with MCI while performing a cognitive task.
METHODS: Fifty-one patients with MCI were recruited and randomly assigned into three groups: a resistance exercise (RE) group (n=17, 65.36±5.18 yrs), an aerobic exercise (AE) group (n=17, 66.15±7.98 yrs), and a control group (n=17, 66.29 ± 6.93 yrs). The neurocognitive indices (e.g., reaction time (RT), accuracy rate (AR), and ERP P3 component) were measured when the participants performed a task-switching paradigm at baseline and after either a 16-week period of moderate-intensity RE or AE intervention, or a control period. Blood samples were taken before and after the exercise intervention.
RESULTS: The RE and AE not only benefited RT and AT performance, but also enlarged the ERP P3 amplitudes in the patients with MCI (all ps<.05). In terms of metabolic biomarkers, post- relative to pre-intervention, the serum insulin level decreased significantly in the AE group (p=.015), although there was only an approaching significant decrease in the RE group (p=.061) and an approaching significant increase in the control group (p=.059). However, RE and AE did not improve the levels of serum leptin in the patients with MCI. The correlations between the changes in the ARs in switching condition and the levels of insulin approached significance (r=-0.5, p=.069) in the AE group.
CONCLUSION: Neurocognitive performances through regular resistance and aerobic exercise modes could be enhanced in the patients with MCI, suggesting that such individuals at this stage of the neurodegenerative disease still exhibit brain neuroplasticity. Although both RE and AE could reduce insulin levels in the patients with MCI, AE may be more effective on improving metabolic indices in this neurodegenerative disease as compared to RE.

DO PEOPLE WHO EXPERIENCE FEAR OF FALLING REDUCE THE AMOUNT OF PHYSICAL EXERCISE THEY DO? A PILOT STUDY

DIMAKOPOULOU, E., BOUZINEKI, C., KARYDAKI, M., MARGIOTI, E.

ATHENS ALZHEIMER ASSOCIATION

INTRODUCTION:Fear of falling (FOF) is the lack of self confidence that daily activities can be performed without falling. Falling is higher in women and increases with age (Arfken et al., 1994, Scheffer et al., 2008). As a result of FOF physical inactivity and reduced participation in physical exercise programs have been observed (Pollock et al., 2012). The aim of the study was to investigate whether the physical activity amount and actual balance will be different between adults with and without FOF.
METHODS: Participants were older adults over 64yrs who visited the memory clinics of the Athens Alzheimer's Association. Demographic characteristics and falls history were collected. Mini Mental State Examination (MMSE) was given to all individuals. PASE questionnaire for physical activity, Falls Efficacy scale (FES-I) and Activity specific Balance Confidence scale (ABC) were administered to individuals free of memory problems or cognitive impairment. Balance was measured using Berg Balance scale (BBS). Participants were divided into two groups based on ABC score. Participants with ABC >80 were placed into no fear for falls group (NFFG). Whereas, subjects with ABC <80 were placed into fear of falls group (FFG). Analysis of variance (Welch's test for unequal variances) was used to examine the differences between the two groups. Level of significance was set at $p<0.05$.
RESULTS: 41 participants of NFFG (10 males, 31 females, aged: 69.1±5.4yrs, height: 1.64±0.07m, weight: 73.9±14.1kg) had ABC score 94.9±4.04, and 17 of FFG (3 males, 14 females, aged: 74.8±5.8yrs, height: 1.62±0.7m, weight: 72.1±13.6kg) had ABC score 65.8±19.06. Differences between NFFG and FFG were found for age ($p=0.002$), falls history ($p=0.02$), FES-I ($p=0.001$) and PASE ($p=0.004$). No difference was found for actual balance (BBS, $p=0.07$).
CONCLUSION: Based on our results older individuals with fear of falling (FFG) were found to have poorer physical activity compared to those without fear of falling (NFFG). Participants of FFG were older and this result is in accordance with previous studies reporting FOF to increase with age (Scheffer et al., 2008). Actual balance (BBS) was not different between the two groups suggesting that FOF is the main reason for reduced physical activity, and not the lack of actual balance. Study limitations are that additional factors such as depression, effect of medications, lower limbs strengths were not included. Strategies to reduce FOF and increase confidence may be beneficial in order to improve the daily function of the elderly.

CHILDREN'S AFTER SCHOOL SPORTS PARTICIPATION: ASSOCIATION OF PARENTAL ATTITUDES AND CHILDREN'S SEDENTARY BEHAVIOR

CHEUNG, P.

THE EDUCATION UNIVERSITY OF HONG KONG

Introduction
After-school sport (AFS) participation is beneficial to children's health. However, academic pressure makes parents prioritize academic-oriented activity, which is sedentary in nature, for their children during after school hours. Parental attitude towards AFS is decisive on the arrangement of physical activity (PA) for children. The purposes of this study are: 1) to compare parental attitude on AFS benefits and children's AFS participation; 2) to compare parental attitude on the benefits of AFS (i.e., on academic and health) and children's sedentary behavior
Methods
Participants were 242 children (131 boys, 111 girls; mean age = 8.7) from five elementary schools and their respective parents. Children's PA level was measured by accelerometer for four normal school days. Questionnaires were completed by parents about their perception on children AFS participation and to report if their children had participated in AFS class in the academic year. ANOVA was conducted to compare the parent's attitude on the benefits of AFS on academic and health (using a seven-point scale) and children's AFS participation (with or without). Parental attitude on the AFS benefits were grouped into positive, neutral and negative (academic benefit) and positive and negative (health benefit) for further analysis.
Results
Children with AFS participation were found significantly with parents who view positively on the AFS benefits on academic (with =5.35 ; without = 4.91, $p=0.014$), and positively on the AFS benefits on health (with =6.40 ; without = 6.02, $p=0.014$). Regarding the PA behavior, children with parents who view positively on AFS benefits on academic found to involve significantly fewer sedentary behavior during after school hours (positive = 100.6 min; neutral = 102.1 min; negative = 118.8 min, $p=0.035$), and within a day (positive = 522.7 min; neutral = 569.8 min; negative = 569.8 min, $p=0.009$). Children with parents who view positively on AFS benefit on health were found to involve significantly fewer sedentary behavior within a day (positive = 538.0 min; negative = 604.0 min, $p=0.001$)
Conclusion
Parental attitude towards AFS participation differentiated children's AFS participation and the children's sedentary behavior. The findings imply the importance to include strategy that may change parental attitude on the benefits of AFS, which will be important to the PA intervention design.

RELATIONSHIP BETWEEN AEROBIC FITNESS AND PERFORMANCE IN MULTIPLE DOMAINS OF EXECUTIVE FUNCTIONS IN ADOLESCENTS

BARROS, J.F.1,2, CABRAL, L.L.P.1, BROWNE, R.A.V.1, COSTA, E.C.1, SOUTO, G.C.1, SCHWADE, D.1, DANTAS, M.1, FREIRE, Y.A.1, FARIAS-JUNIOR, L.F.1, LIMA, F.A.S.1, LIMA, M.N.M.1, SILVA, A.R.2

1FEDERAL UNIVERSITY OF RIO GRANDE DO NORTE, 2UNIVERSITY OF BRASÍLIA.

INTRODUCTION:Executive functions (EFs) refer to a set of cognitive processes responsible for maintaining behavior, emotion and thoughts, which develops from early childhood and through adolescence to adulthood (1). These functions are all crucial skills for success in all of

life's aspects, such as learning and academic achievements (1). Physical activity is a behavioral factor that can promote beneficial effects on brain health and cognition, even during adolescence (2). This occurs due to its effects on the human body, mainly on the cardiovascular and cerebrovascular system (2). Therefore, this study aimed to investigate the relationship between aerobic fitness and performance in multiple domains of EFs in adolescents.
METHODS: One hundred and thirty-two school-aged adolescents (57 girls) aged 11–16 years participated in this cross-sectional study. Each participant completed a progressive aerobic cardiovascular endurance running (PACER) test, computerized cognitive tests (Tower of London, Berg's Card Sorting Task, Go/No-Go Oddball, Sternberg's Working Memory Search, and Attentional Network Task) and questionnaires for daytime sleepiness, as well as other factors that might influence cognitive performance (age, gender, pubertal stage and body mass index). The multiple linear regression analysis was used to inspect PACER laps as a continuous predictor of each cognitive outcome adjusted for age, gender, pubertal stage, body mass index percentiles, and daytime sleepiness score. Afterwards, the hierarchical linear regression analysis was used to determine the moderating gender effect on the relationship between aerobic fitness and cognitive performance.
RESULTS: Higher aerobic fitness was associated with better metacognitive performance, which was assessed through planning time (B = -23, 95% CI -45 to -1, p = 0.041) and solution time (B = -50.2, 95% CI -99.9 to -0.4, p = 0.048) in performing the Tower of London task. There was a moderating gender effect only for the cognitive flexibility ($p < 0.05$). Higher aerobic fitness was also associated with better performance in completed categories (B = 0.05, 95% CI 0.01 to 0.1, p = 0.013) and persistent errors (B = -0.21, 95% CI -0.39 to -0.03, p = 0.020) in performing Berg's card sorting test only for girls. There were no relationships found for Go/No-Go Oddball, Sternberg's Working Memory Search, or Attentional Network Task (ps > 0.05).
CONCLUSION: The findings suggest that higher aerobic fitness level was associated with better metacognition in adolescents, independent of gender. Moreover, we observed a positive relationship between aerobic fitness and cognitive flexibility only in girls.

PHYSICAL, COGNITIVE AND DIETARY CHARACTERISTICS OF OLDER WOMEN WITH MUSCULOSKELETAL AMBULATION DISABILITY SYMPTOM COMPLEX (MADS)

KIMURA, Y.
INSTITUTE OF FITNESS AND HEALTH SCIENCES

INTRODUCTION:To examine physical, mental and dietary functions of older community-dwellers using balance assessment, physical, and cognitive function tools, and eating habit questionnaire and understand the MADS in older women.
METHODS: Eighty-six women aged 65 years and over (mean age 71+3 yrs.) participated in this study. The participants completed a demographic questionnaire, one-leg standing time with eyes open (OLS) and timed up-and-go test (TUG). Then, they were divided into two groups according to OLS: G1) longer than 15 sec. (n=61,) and G2) less than 15 sec. (n=25). Following items were measured: hand-grip strength, chair-stand, functional reach, gait speed as physical function, Mini-Mental State Examination (MMSE) and Trail Making Test-A (TMT-A) as cognitive function, and brief-type self-administered diet history questionnaire (BDHQ) as examining eatig habits.
RESULTS: The average time of OLS was significantly differenint in G1 and G2 (72.7+58.0 and 7.6+ 3.9 sec., $p<0.01$). Age was significantly different in G1 and G2 (70.2+2.5 vs. 73.2+ 4.4 yrs., $p<0.05$). The results show that maximal gate speed and TUG was significantly lower in G1 than G2 (1.73+0.24 vs. 1.87+0.28 m/sec., $p<0.01$) and (6.8+1.1 vs. 7.5+1.5 sec., $p<0.01$). BDHQ revealed that the consumption of marine products (34.4+43.3 vs. 5.0+2.5 g, $p<0.01$) and cooked fish (25.7+30.4 vs. 5.6+3.5 g, $p<0.01$) were significantly higher in G1 than G2 . Older adults without MADS consumed more marine products and cooked fish. In ANCOVA adjusting for the age, only TMT-A was significantly different in G1 (86.2+25.2 sec) and G2 (98.4+28.5 sec.), $p<0.01$. MADS may affect the TMT-A in the older women living in Japan.
CONCLUSION: These results suggest that decline in physical, dietary and cognitive functions may be associated with MADS in older women.

STRATEGIC SPORTS PROGRAM ENHANCES TASK SWITCHING PERFORMANCE IN CHILDREN WITH INTERNET ADDICTION

HUNG, C.L., TSENG, Y.H., CHAO, H.H., KANG, C.N.
DEPARTMENT OF ATHLETICS, NATIONAL TAIWAN UNIVERSITY

INTRODUCTION:The purpose of this study was to examine whether a strategic sports program improved cognitive flexibility evaluated by task switching among children with internet addiction.
METHODS: Ten school-aged children were recruited through the flyer and screened by the Chinese Internet Addiction Scale. Participants were assessed by task switching and motor ability prior to and after a 12-week strategic sports program intervention (twice per week, 90 min per session).
RESULTS: Significant improvements in accuracy associated with the pure, mixed, and switching trials and nearly significant in the manual dexterity component and the total standard score of motor skills were observed in the post-test comparing to pre-test.
CONCLUSION: Data from this one group pretest-posttest design support that strategic sports program intervention is a feasible and effective behavioral approach to enhance cognitive function and motor skills in children with internet addiction. The future study including a control group, preferably an RCT design will be needed to validate the findings of the present study.

THE RELATIONSHIP BETWEEN ERROR MONITORING AND COOPERATIVE LEVELS IN ATHLETES WITH DIFFERENT GROUP SIZES: FROM THE PERSPECTIVES OF NEUROCOGNITIVE PERFORMANCE

RUO-WEI, L., CHIA-LIANG, T.
NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION:As a division of social roles, cooperation is the necessary way for human survival and development (1). Cooperation can significantly enhance the profits when compared with noncooperation (2). However, no studies have yet been conducted on the effect of cooperative levels on neurocognitive performance in athletes with different group sizes. The aim of the present study was thus to explore

the relationship between error monitoring and cooperative levels in athletes via event-related potentials and behavioral measures while performing a cognitive task.
METHODS: Forty male athletes aged between 20 to 30 years (M = 22.90, SD = 2.33) were recruited from different types of sports at National Cheng Kung University. Cooperative levels mean the number of partners when the athlete is playing a sport. The neurocognitive indices [e.g., accuracy rate (AR), reaction time (RT), and error-related negativity (ERN)] were simultaneously measured when the participants performed a stroop task. Three models were used in this study: Linear (Model 1), Quadratic (Model 2) and Cubic (Model 3).
RESULTS: Only Model 2 revealed a significant effect of cooperative levels in athletes with different group sizes [b = -.177, t (39) = -2.79, p = .008], such that 4 partners elicited smaller (more positive) ERN amplitudes at Fz and FCz electrodes than any other number of partners. The regression analysis in Model 3 revealed a significant effect. However, there were no significant effects in all coefficients except the constant.
CONCLUSION: Overall, these data suggest that the athlete with 4 partners showed the worst error-monitoring ability than the others. In addition, according to the analysis as mentioned above, more partners, when the number is larger than 4, showed better neurocognitive performance.

EXAMINING EMOTIONAL FACIAL EXPRESSIONS IN VOLLEYBALL

VAGO, P.1, LUCARELLI, F.1, MARZARI, L.2, GENTILESCHI, V.2
1_DEGREE COURSE IN MOTOR SCIENCES, CATHOLIC UNIVERSITY, MILAN 2_ I&G MANAGEMENT, MILAN

Introduction:
Paul Ekman's interests have focused on nonverbal behaviour and communication, specifically on the expression and physiology of emotions. His studies demonstrated that we show, through facial expression, seven emotions in a universal way: fear, sadness, happiness, anger, contempt, disgust and surprise. These expressions can appear in any social context, including the sports field.
The aim of this study was to explore if facial expression and related emotions are connected with positive or negative results during competition in team sport events.
Methods:
In this preliminary study we video recorded and analysed (slow motion review using Kinovea 0.8.15 program) all winter matches of a professional female Volleyball Team, Igor Volley Novara, the Italian Serie A1 Championship winner in 2017. We chose two emblematic matches: the worst one in the season (lost 0-3) and the best one (won 3-0). All video frames were analysed with the FACS coder (Facial Action Coding System), a Paul Ekman's methodology used to codify all the possible human facial expressions.
Results:
The results of this preliminary study shown some interesting correlation between emotions and performance: the marker "Eye of the Tiger" (subtle expression of controlled anger/determination/focus on the match) is inversely related to victory, and this could also be applied to the facial expressions of disgust. Another interesting result is concerns the happiness/relief facial expressions: happiness and exhilarating joy when the team score a point during the playtime could be helpful for managing stress during all the game. In lost matches the scores were similar to those obtained in which the match was won, but different behaviour and mindset (gloating gaze related to winning points) were more frequent in the won match compared to the lost match.
Conclusion:
The impact of emotional skills in sports performance (being able to recognize ones emotions, being able to manage them and recognize them in others) enables the athlete to better manage stress situations that may occur during training and sport competition. At the same time, the consideration of emotional skills by the coach could help to achieve a better approach with the team. Learning to identify emotions in their early stages is likely to improve communication with athletes in a variety of situations.

CONSIDERATION OF CAUSAL RELATION BETWEEN INDUSTRY AND EXERCISE COMPETENCE: IN FOURTH GRADE PE BALL GAME UNITS

MURASE, K., AMBE, H.
WAKAYAMA UNIV.

INTRODUCTION:Recently, there are many researches that Non-cognitive skill in childhood has great impact to income and health status in adulthood. The purpose of this study was to clarify causal relationships between factors of the Industry Scale for Physical Education (ISPE: Industry means diligence which is one of the stages of Erickson's psychological development) and factors of the Physical Competence Scale (PCS) through a unit of ball game in physical education classes.
METHODS: Fourth grade Elementary school students in four classes (N=126, 62 boys and 64 girls in total) participated in the ball game unit. Participants completed the questionnaire which consisted of ISPE and PCS before and after the unit. The factors of ISPE are (1) empathy for peers, (2) discovery of challenge, (3) initial remark and (4) Conscientiousness. There is a moderately correlation between Conscientiousness of ISPE and Flow experience. Also, the factors of PCS are (1) perceived physical competence, (2) feeling of control and (3) peer and teacher acceptance.
RESULTS: Conscientiousness and Discovery of Challenge factors in the ISPE and Physical Competence and Feeling of Control factors in the PCS were utilized following analysis. These two factors of ISPE showed moderately correlations toward Flow experience (Conscientiousness: r=.64, Discovery of Challenge: r=.51). In addition, since analysis was aimed at clarifying causal relationships between four factors which is already mentioned within the unit of ball game classes, we used only the Synchronous Effect Model (Structural Equation Modeling). The results were as follows. The Synchronous Effect Model revealed that Conscientiousness effects on Discovery of Challenge(β=.37), Feeling of Control(β=.25), and Physical Competence(β=.19). At the same time, it was also revealed that Feeling of Control effects on Conscientiousness (β=.19).

CONCLUSION: These results means that industriousness reinforces physical competence, also there was a cyclical process between Conscientiousness and Feeling of Control. In conclusion, enhancing sport competence through Flow experiences which are accompanied by efforts and immersed experiences seems an ideal way to develop intrinsic motivation and physical literacy.

THE EFFECT OF STUDENTS' INTENTIONS TO TAKE A BASKETBALL CLASS ON THEIR SHOOTING SKILLS AND LEARNING EFFECTS

KONNO, R.

J. F. OBERLIN UNIVERSITY

INTRODUCTION:The purpose of this study is to assess how students' intentions to take a basketball course are related to their shooting skills and learning effects.
METHODS: The participants were 55 college students taking a basketball course. Intentions to take the course, sports that they used to play for schools, and shooting skills were assessed. Regarding shooting skills, two types of shooting (i.e., shooting close from the basket and layups after dribbling) were measured at the beginning and end of the course.
RESULTS: T-tests were conducted to assess the relationship between the numbers of baskets they made and their intentions to take the course. The result showed that their intentions to take the course, classified as "I like basketball," "this course is required for my health and physical education teaching profession curriculum," and "I like sports," leaded to the differences in their shooting skills. T-tests were completed to investigate how students' intentions to take the course would influence their improvement in the numbers of baskets that they made. Regarding shooting close from the basket, those who have intentions of "I like sports" or "this course is required for my health and physical education teaching profession curriculum" improved the numbers of baskets they made and thus produced learning effects. On the other hand, regarding layups, students whose intentions were "improving skills" and "this course is required for my health and physical education teaching profession curriculum" had significantly fewer numbers of baskets they made than students who did not have those intentions.
CONCLUSION: Students who selected "I like basketball" as their intentions to take this course were those who used to play basketball for their schools. Therefore, they previously had great basketball experience and possessed some basic skills, and this fact might directly influence on the result. Those with the intentions of "this course is required for my health and physical education teaching profession curriculum" did not have any particular sports they used to play for their schools. Therefore, they seemed to make effort to increase their shooting skills to meet their requirements to receive a teaching license. That might relate to the context of learning effects. The majority of the students who did not select "I like sports" as their intentions were those who used to play basketball for their schools, but those who selected "I like sports" as their intentions liked sports in general and did not have any advanced skills in basketball. That might increase their seriousness and motivation to practice and then improved their skills.

THE EFFECT OF DART TRAINING ON COGNITIVE FUNCTION OF ELDERLY PEOPLE

KAZUMA, F., FUMIAKI, M., RYOTA, H., MITSUKI, K., MASAKI, T.

DOSHISHA UNIVERSITY

INTRODUCTION:We hypothesized that wellness-dart training which include planning, judgement, execution and calculation when conduct dart exercise could be effective for preventing the decline of cognitive function in the elderly. The aim of this study was to examine how dart training affect cognitive function on elderly people in both longitudinal and cross-sectional stand points of view.
METHODS: In the longitudinal study, we prescribed dart training for elderly (n = 15, 74.1 ± 3.5 yrs) for 12 months. In order to evaluate cognitive function, we performed calculation test, short-term memory (STM) test, cognitive flexibility test (WCST), and dexterity test at 0 month, 3 months, 6 months, 12 months. In the cross-sectional study, the subjects who has continued dart training for more than 6 months (n = 30, 72.5 ± 3.5 yrs) were selected as dart training group and cognitive function of this group was compared to no dart control group (n = 26, 73.2 ± 3.8 yrs). One way analysis of variance test was used for longitudinal study and unpaired t-test was used for cross-sectional study.
RESULTS: As a result of the longitudinal study, STM test significantly improved from 0 month to 6 months ($P < 0.02$) and to 12months ($P < 0.01$). Calculation test did not changed from0 months to 6 months, but significantly decreased from 6 months to 12 months ($p < 0.05$). The cross-sectional study revealed that calculation test and the STM test of darts training group were significantly higher than that of control groups.
CONCLUSION: As a result of longitudinal study, it was suggested that dart training for more than a half year improves short term memory in the elderly. Cross-sectional study revealed that dart training can make the elderly people well status in arithmetic calculation ability and short term memory. From the results of both studies, it could be said that dart training might be an effective means to suppress the deterioration of cognitive function with aging in elderly people.

APPLICATION RESEARCH OF OF HRV AND SPORTS PSYCHOLOGY INDEX TO MONITOR SPORTS FATIGUE OF BOXING ATHLETES

WANG, J.H., QIU, J.

SHANGHAI RESEARCH INSTITUTE OF SPORTS SCIENCE

INTRODUCTION:Heart rate variability (HRV) was sensitive to autonomic nervous system function and changed with the increase of training load, the test and analysis of HRV could reflect the adaptation of cardiac autonomic nervous system to exercise during the recovery period after exercise. HRV was often used to monitor sports fatigue and prevent overtraining because of convenience and measurability. When sports psychological fatigue occurred, HRV index changed to different degrees, and the synergistic effect of sympathetic and parasympathetic nerves on the heart changed after fatigue, HRV was also used to evaluate sports psychological fatigue. Therefore, to observe the changes of heart rate variability index and sports psychology index before and after 4-week heavy load training in boxing athletes, this study was to explore the application of these indicators in monitoring sports fatigue.
METHODS: 6 athletes (23.3±3.1yrs) from Shanghai mens boxing team were recruited. The coach scheduled a 4-week heavy load training, the heart rate variability (HRV) indexes were monitored on Monday morning before and after the 4-week training, and Athlete Burnout Questionnaire (ABQ) and Profile of Mood States (POMS) were investigated as well, these indexes were used to evaluate the sport fatigue. The data statistics was processed by SPSS 22.0, and paired T test was used to compare the experimental data.

RESULTS: 1) After heavy load training, POMS index indicted that depression and panic were significantly increased ($p<0.05$), while energy, self-esteem, tension, anger and fatigue were not statistically significant compared with that before training ($p>0.05$), the mood and emotion tended to be disturbed. 2) After heavy load training, sense of achievement decreased, negative evaluation of sports, and Z-weighted total score of psychological fatigue increased significantly compared with that before training ($p<0.05$, $p<0.05$, $p<0.01$). 3) After heavy load training, lnLF and LF/HF of athletes HRV indexes were significantly increased ($p<0.05$), while lnTP, lnHF, lnSDNN, lnRMSSD, lnPNN50 and lnVLF were not statistically significant compared with that before training ($p>0.05$).
CONCLUSION: After heavy load training, the boxing athletes mood and emotion were confused, which was characterized by the increase of depression and panic value, and the aggravation of sports psychological fatigue was characterized by the increase of sense of achievement decreased and negative evaluation of sports. The lnLF and LF/HF were increased after heavy load training, suggesting that the imbalance between sympathetic nerve and parasympathetic nerve tend to be dominant in sympathetic nerve activity. Changes in LF and LF/HF of some HRV indicators were synchronized with sports psychological indexes, which can monitor sports fatigue of boxing in combination with sports psychological indexes.

PSYCHOLOGICAL INTERVENTION IN MARATHON RUNNERS: MANAGING NEGATIVE SITUATIONS

RENFREE, A., JAENES, J.C., CASADO, A.

UNIVERSITY OF WORCESTER

Psychological intervention in marathon runners: Managing negative situations
Renfree, A., Jaenes, J.C., & Casado, A.
1. University of Worcester 2. Pablo de Olavide University 3. Isabel I de Castilla University
Introduction
Running 42,195 meters is considered a difficult task (Jaenes & Caracuel, 2016). Anxiety, lack of self-confidence, and negative thoughts are frequently experienced by long distance runners. Several researchers have developed different Psychological Skills Training (PST) (Weinberg and Gould, 2014) techniques in order to allow runners to better cope with these stressful situations (Jaenes & Caracuel, 2001; 2016).
Methods
Participants were eight male runners (27.6 + 5.06 years) with 14.75 + 3.85 years of running experience and who had run at least 3 marathons prior to the study. Over seven weeks, participants practised PST techniques (one hour per week), prior to the 2017 Sevilla Marathon. PST consisted of Relaxation and Stop Thinking strategies, and Attentional Cognitive strategies (ACS, Association and Dissociation). Jacobson Relaxation (JR) and Stop Thinking (ST) Technique Evaluation Worksheets were utilised. Runners practised JR once every day, and ST in three different situations:, at home (twice a day), during training when negative thoughts occurred and when they lost concentration. Additionally, at every training session, runners provoked the negative thoughts and distraction (dissociation) and were asked to attempt to stop the thoughts and concentrate on the race (association). Pre-test and post-test assessment of perceived negative mood states prior the race, perceived negative thoughts during the race, mental overload and doubts were performed using a Likert Scale. A Wilcoxon signed-rank test for dependent samples was conducted to check whether pre-post results were statistically significant, and Spearman correlation was conducted to check the interdependence of the measurements. Data analysis was performed using SPSS 24.0.
Results
There was a significant decline in negative perceived mood states prior to the race ($z =-2.55$, $p <.05$), having checked for interdependence ($r =0.67$, $p >.05$). Significant differences in negative mood states during the race were also found ($Z =-2.52$; $p <.05$), having checked for interdependence ($r =-.385$, $p >.05$). Additionally, differences in mental overload and doubts were observed ($z=-.253$, $p <.05$), but no interdependence was demonstrated ($r =-.793$, $p <.05$).
Conclusion
Seven weeks of PST was effective in managing anxiety, negative thoughts and distraction in experienced marathon runners.

THE ASSOCIATION BETWEEN ENERGY BALANCE RELATED BEHAVIOUR AND BURN-OUT IN ADULTS: A SYSTEMATIC SCOPING REVIEW

VERHAVERT, Y., DELIENS, T., VAN DER LINDEN, E., VAN HOOF, E., ZINZEN, E., DE MARTELAER, K.

VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION:Over the last decades, the prevalence, but also the recognition of burn-out increased enormously. To reduce the high and still increasing incidence and prevalence of burn-out, effective interventions are needed. Although it is believed that physical activity, dietary, and sedentary behaviour (i.e. energy balance related behaviour) may decrease the risk for or even prevent burn-out, the association between both is currently not well understood. Therefore, the aim of this systematic review was to make an overview of studies investigating the relationship between energy balance related behaviour and burn-out.
METHODS: A systematic literature search was conducted in PubMed, Web of Science, Embase and PsycINFO. Results were limited to original English written articles, published in full-text format in peer reviewed journals until January 2019. Studies investigating other affective disorders than burn-out (e.g. bipolar disorders), including non-working adults, or investigating the association between alcohol or disordered eating behaviours and burn-out were excluded.
RESULTS: In total, 23 studies were found, including 13 observational and 10 interventional studies. Of these, five were randomized controlled trials (RCTs). Twenty-two studies examined the link between physical activity and burn-out, whereas one study investigated the link between both physical activity and diet and burn-out. No studies assessing the relationship between sedentary behaviour and burn-out were found. Twelve observational studies found a negative association between physical activity and burn-out, whereas one study did not find a relation. The single study on diet and burn-out reported a negative relationship between a healthy diet at working days and burn-out. Six of the interventional studies, including two RCTs, showed that exercise programs were effective to reduce burn-out levels. Four interventional studies, including three RCTs, did not find any influence of exercise programs on burn-out. Across both observational and interventional studies there was also a lot of heterogeneity regarding physical activity assessment and exercise programs, respectively, and burn-out.

CONCLUSION: Although the vast majority of observational studies suggest that higher levels of physical activity may lower levels of burn-out, the included interventional studies did not consistently confirm this hypothesis. Two out of five RCTs showed that physical activity was effective in reducing burn-out levels. Due to the scarcity of high-quality research (i.e. RCTs), as well as the heterogeneity between studies, it is difficult to draw any firm conclusions, especially when it comes to causal inference. Moreover, research on the association between dietary and sedentary behaviour and burn-out is urgently needed. We may therefore conclude that more high-quality research is needed to unravel the energy balance related behaviour-burn-out relationship.

DIFFERENCES IN PACING AND COGNITIVE STRATEGIES USED BY TRAINED AND UNTRAINED ATHLETES DURING ALONE AND COMPETITIVE 16.1KM CYCLING TIME TRIALS

WILLIAMS, E.L.1, MASSEY, H.S.2, WHITEHEAD, A.3, MARCHANT, D.4, POLMAN, R.5

LEEDS BECKETT UNIVERSITY 1, UNIVERSITY OF CENTRAL LANCASHIRE 2, LIVERPOOL JOHN MOORES 3, EDGE HILL UNIVERSITY 4, QUEENSLAND UNIVERSITY OF TECHNOLOGY 5

INTRODUCTION:Expertise differences in cognition allows identification of how experience influences in-task cognitive strategies and decisions to alter work-rate. Whilst an awareness of competitors is an important source of information for meta-cognitive performance regulation (Brisk et al., 2014), their behaviour is interpreted in line with personal capacity (Baker, Côté, & Deakin, 2005) and continuously monitored through internal and external feedback. This study aimed to compare differences in performance and cognition between trained and untrained participants during alone and competitive time trials (TT).
METHODS: Eight trained male cyclists (age = 48.5 ± 14.6 yrs;) and ten untrained, physically active males (age = 34.9 ± 5.9 yrs;) performed three 16.1km cycling time trials on separate visits; an initial baseline TT (BL), an alone TT (AL) and one against a visually presented avatar competitor, unknown to them to be representative of their baseline performance (COMP). Feedback sources (speed, power, time, distance and heart rate) were presented throughout the trials. Participants were instructed to use Level 2 Think Aloud, verbalising all thoughts during performance, transcribed to assess cognition.
RESULTS: The trained group performed both TTs in a significantly faster time than the untrained group ($p < .001$) with no differences between the AL and COMP for either group. A significant quartile v group interaction for pace ($p = .013$) showed differences between groups at 8km ($p = .026$) and at 12km ($p = .031$). The total number of verbalisations did not significantly differ between groups ($p = .149$). There were no significant differences between trials for any primary or secondary themes in either group ($p > .05$). Active Self-Regulation (ASR) was the most verbalised theme for both groups, with the trained group verbalising more ASR thoughts during COMP than the untrained group ($p = .049$). For primary themes, during COMP the trained group verbalised more thoughts of Power than the untrained ($p = .015$), whereas the untrained verbalised more thoughts of Pace ($p = .013$). The untrained group verbalised significantly more thoughts of Pace, Technique and Time in the ALONE trial than the trained ($p \leq .033$). Both groups verbalised more about Motivation in the final quartile of the ALONE trial ($p \leq .046$), and the trained group in the COMP trial ($p \leq .028$).
CONCLUSION: Competition had no effect on pace or cognition for either group. Regardless of condition, expertise groups pace themselves differently during the middle portion of the trial. Expertise differences were also found in Active Self-Regulation (Power, Pace, Technique) and Outward Monitoring (Time) cognition during both conditions. Despite little effect of competition, there are important in-task cognitive strategy differences between trained and untrained cyclists that require further investigation.

«PHYSICAL ACTIVITY HAS BECOME FUN» - ENHANCED MOTIVATION THROUGH A PLAY-BASED EXERCISE INTERVENTION IN ADOLESCENTS WITH ASTHMA

BRYNJULFSEN, T.1, DEMMELMAIER, I.1,2, BERNTSEN, S.1, FOYN, T.H.1, ANDERSEN, O.K.3, STANG, J.3, SIGDESTAD, J.B.1, WESTERGREN, T.1

1: UNIVERCITY OF AGDER 2: UPPSALA UNIVERSITY, 3: NORWEGIAN SCHOOL OF SPORT SCIENCES

INTRODUCTION:The objective for this study was explore how adolescents with asthma describe their motivation for physical activity before and during participations in a 10-week play-based exercise intervention.
METHODS: Eighteen adolescents with asthma, aged 13- 17 years, participated in a 10- week play and interval-based exercise intervention. The intervention was indoor during winter months and led by sports students. Semi-structured focus group interviews were conducted in week 2 (n=18) and week 8 (n=14). The first interview focused on experiences related to asthma, abilities, and limitations of physical activity. The second interview focused on experiences, limitations, and the social interaction between the participants and instructors within the intervention. Field observations were also conducted in week 2 and 8 and focused on how participants expressed, and presented themselves, and interacted with each other and instructors concerning their asthma disease, abilities, limitations, and the various physical activities. The interviews were transcribed verbatim and analyzed using thematic analysis with a deductive approach using self-determination theory as a starting point. The second interview and the descriptive observational data were analyzed separately from the first interview.
RESULTS: In the first interview participants reported amotivation for physical activity related to barriers such as: asthma symptoms and teachers' lack of facilitation when they are experiencing asthma symptoms, cold air and pollen, embarrassment, and not being able to keep pace with peers. Intrinsic motivation for physical activity was related to mastering the physical activities and that these were perceived as fun. Within the intervention, based on the second interview and descriptive observational data, intrinsic motivation for physical activity was enhanced by relating to peers with asthma, instructor's with asthma knowledge, the variety of different physical activities of the intervention, enjoyment, and a sense of mastery. Competitive games while instructors encouraged effort rather than results led to enhanced effort and motivation for physical activity.
CONCLUSION: A 10-week play-based exercise intervention was reported and observed to be supportive of intrinsic motivation, enjoyment and mastery, and reduced social and asthma specific barriers.

CAN THE EXTRA PHYSICAL ACTIVITY ENHANCHE THE PSYCHOLOGICAL AND COGNITIVE FUNCTIONS?

RUSSO, G., NIGRO, F., CECILIANI, A.

UNIVERSITY OF BOLOGNA

INTRODUCTION:This study aimed at investigating whether the Extra Physical Activity (EPA) has a chronic impact on the psychological functions such as self-esteem and the ability to storage information. In the recent literature the acute effect of the intense cardiovascular activity has been already shown as a mean to enhance the cognitive functions (e.g. memory capacity, 1).

METHODS: 4 classes of a Rimini school participated to the study. In total 76 students (12.86 y ± 0.62) were tested. 39 female and 37 male students performed filled the self-esteem questionnaires (Rosemberg, 1960) and performed a Free Memory Recall Test (FMRT). The students were divided according to gender, self-esteem and EPA. The EPA consisted in the participation, after school, in different activities organised by the school such as frisbee and dancing. An ANOVA was performed to assess the differences between groups in self-esteem. The MANOVA were run in order to test the memory skills (Memory Tasks 1, 2) for gender, self-esteem and EPA score
RESULTS: Data analysis revealed a significant triple interaction (Self-esteem X EPA X Gender, F=8.65, p<.01). EPA male participants reported a higher score in self-esteem compared with EPA female students (31.3±3.4 vs 27.3±4.45, p=.03) and males who did not take part to EPA (27.5±3.74, p= .04). The MANOVA for the two memory tasks highlighted significative interaction only for Self-esteem score (F=5.55, V=.14, p=.006). Difference were also detected in the Gender (p = .72) and Gender X Self-esteem (p=.08), but they were not significant. The post-hoc ANOVA in Memory task 1showed a significant interaction for Self-esteem (F=8.32, p<.01). No differences emerged from the post-hoc ANOVA for self-esteem (p=87) in Memory task 2. Students with high self-esteem performed memory 1 task better than low self-esteem (11.6±3.1VS 9.86±2.3).
CONCLUSION: The male students who took part to the EPA seemed to have higher self-esteem scores than their counterpart that did not participated to the extra activities. As well as differences emerged between males and female who practiced the EPA. The memory tests results did not revealed differences between the EPA and non-EPA groups, but student with high Self-esteem were able to remember more words than low self-esteem students. The results of self-esteem are in line with literature that supports a higher score in active students (2). Moreover, the difference between males and females as already found by other researchers in similar investigation (3). The FMRT was better performed by the higher self-esteem score's students. While no difference emerged between who participated in EPA or not, in FMRT results. This could probably due to the small sample size took into considerations by us. For future investigations the sample size should be incremented, and the physical activity should be standardized differently.

RELATIONSHIP BETWEEN COMPETITION EXPERIENCE AND LIFE SKILLS IN COLLEGIATE CHEERLEADERS

YAMADA, Y., TSUCHIYA, H.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION:Cheerleading is an aesthetic sport whose distinguishable aspect is a stunt, bases' lifting or tossing flyers to perform tricks in the air. As is well known, life skills can be acquired through sport experience. The purpose of this research was to reveal the relationship between competition experience and life skills in collegiate cheerleaders.
METHODS: In July and December 2018, while the national competition was held in December, 68 female cheerleaders (mean age = 19.34 ± 1.15) completed two online surveys using Appraisal Scale of Required Life Skills for College Athletes (Shimamoto et al., 2013). This scale covers 10 factors of life skills (e.g., maintaining physical health and wellbeing; PHW, taking responsibility for one's own behaviour; RB).
RESULTS: First, participants were categorized based on the competitive level of each team, high competitive teams (HT, n = 37), reached finals of the competition, and low teams (LT, n = 31). The results of MANOVA revealed that the interaction between competitive level and competition experience was marginally significant regarding stress management skills (F (1, 66) = 3.40, p =.07) and PHW (F (1, 66) = 2.95, p = .09). The post-hoc comparison confirmed that cheerleaders in HT acquired higher level of life skills regarding stress management skills and maintained life skills regarding PHW.
Second, participants were divided into two groups by positions, flyers (n = 44) and bases (n = 24). The result of MANOVA revealed that the interaction between positions and competition experience was significant regarding appreciating others (F (1, 66) = 4.29, p = .042) and RB (F (1, 66) = 4.93, p=.030), and marginally significant regarding communication (F (1, 66) = 3.03, p = 0.09). The post-hoc comparison confirmed that bases acquired higher level of life skills regarding these three factors after the competition.
CONCLUSION: Cheerleaders in LT group cannot get enough support both physically and mentally due to shortage of educational staffs, which is considered as a cause of the decline of life skills regarding stress management skills and PHW. For stunting, cheerleaders need to take their responsibilities for playing their roles not only to perform better, but also not to hurt their teammates. During the competition season, bases can realize the importance of showing their appreciation to their teammates, taking responsibility for their roles and communicating within the teams to improve safety and perfection of their performance. These can lead bases to acquire higher level of life skills regarding appreciating others, RB, and communication.

WHAT ARE PSYCHOLOGICAL ISSUES THAT THE ELITE FEMALE ATHLETE HAS? — AN APPROACH TO CONSTRUCT THE PSYCHOLOGICAL SUPPORT PROGRAM —

KONDO, M.

OSAKA UNIVERSITY OF HEALTH AND SCIENCES

What are Psychological Issues That the Elite Female Athlete Has?
— An Approach to Construct the Psychological Support Program —
Midori Kondo1, Seshito Shimizu2, Kisho Zippo1, Hironobu Tsuchiya1
1: Osaka University of Health and Sport Sciences, 2: Sports Design Lab
Introduction
An increasing of female athletes has created a requirement for more gender-specific psychological support. In Japan it was revealed that for the female athlete competitive stressor consist of two factors; "Harassment and Discrimination", "Competitive performance and environment", and daily stressor consist of three factors; "Gender", "Menstruation" and "Maintenance and change in body proportion" (Kemuriyama and Amazaki, 2013). However little empirical research has addressed these issues among elite female athletes. The purpose of this study was to clarify their issues in order to construct the psychological support program.
Methods
First, elite female athletes (N=67) and sub-elite ones (N=80) completed a questionnaire, which was consisted of 54 items of incidents or states to be concerned with their somatic, mental, human relations, competitive performance and environment during the last three months. These items were based on the competitive and the daily stressor stressor scale for female athletes (CSSFA, DSSFA). Each re-

sponse was rated with a five-point scale from "not at all" to "very often". In addition, with an open-ended questionnaire, we asked "What do you feel difficult in the competitive and daily life?" And then a focus group interview was conducted with specialists of sport psychology. The interview explored what were issues to be addressed in the psychological support for the elite female athlete.
Results
We had mainly three results as follows: First, result of t-test showed that the elite group more frequently experienced the situation of few woman staff than the sub-elite group ($t=2.22$, $df=145$, $p<.05$). Second, the description data obtained was classify with the KJ method indicated that the elite female athlete feels it was difficult to play under the pressure that other people was placing high expectations on her, to keep motivate on a competition, and to deal with unarticulated anxiety about menstruation, physical fatigue, career development and transition. Third, the interview data was transcribed and thematically analysed, pointed out the essential features of issues that it was needed for learning accurate knowledge about triad, being awareness of one's physical and psychological state, and improving self-control skills.
Conclusion
This research among female athletes appears frequency of feel stressed for "There are few or no woman stuff." is relatively higher the elite group than the sub-elite group. It suggest that woman with a high degree of specialization, not man, may need to psychological support for the elite athlete. In addition, some issues were clarified out of view of not only the elite female athlete but also specialists of sport psychology. These findings will provide important suggestion for constructing the psychological support program.

DEVELOPMENT OF MENTAL SUPPORT PROGRAM USING PSYCHOLOGICAL COMPETITIVE ABILITY TEST RECALLING THE PAST IN COLLEGE ATHLETES

TAKENO, Y.1, SAITO, Y.2

1: JOETSU UNIVERSITY OF EDUCATION, 2: KANAZAWA SEIRYO UNIVERSITY

INTRODUCTION:It has been reported that psychological factors are important for improving athletes' performance. We took particular note of psychological competitive ability in this respect and previously developed psychological competitive ability test recalling the past (recalling test) for college athletes. The first purpose of this study was to evaluate the validity of the recalling test. Further, we designed a new mental support program using the recalling test. The second aim of the present study was to examine the availability of our mental support program that uses the recalling test.
METHODS: First study: To evaluate the validity of the recalling test, 30 college athletes participated in this study. After a present psychological competitive ability test (first real test), athletes tested psychological competitive ability recalling the past games of a year (first recalling test of a year ago) and of two years (first recalling test of two years ago) ago, respectively. Subsequently, they took the second real test, recalling tests of a year ago and of two years ago after almost a year of first tests. The validity of the recalling test was evaluated by analyzing the degree of match between first and second tests.
Second study: To examine the availability of our mental support program that uses the recalling test, 16 college athletes participated in the mental training program to enhance their mental performance for approximately two months after completing the recalling test. They only took the real test after the training program, and the effects of the training program on their psychological competitive ability were subsequently analyzed.
RESULTS: First study: Their total score on psychological competitive ability test in the second recalling test of a year ago was highly correlated with that of the first real test ($r=0.847$, $p<0.01$). In addition, the total score in the second recalling test of two years ago was highly correlated with that of the first recalling test of a year ago ($r=0.892$, $p<0.01$).
Second study: Their total score on psychological competitive ability test was increased from 169 ± 32 (mean ± SD) before mental training program to 192 ± 21 after the program ($p<0.01$). Moreover, 12 of 16 college athletes attained higher total score after the program compared with the recalling and real tests before the program.
CONCLUSION: In the first study, high degree of match between first and second tests suggests that recalling test might have high validity to assess past psychological competitive ability of college athletes. Also, the results in the second study confirm that our mental support program which combines the mental training with the recalling test is useful because the effects of the training program were comparable to not only pretraining but also past psychological competitive ability in college athletes.

IS GREEN EXERCISE EFFECTIVE: INFLUENCE OF INDOOR AND OUTDOOR EXERCISE ON THE PERFORMANCE OF ENDURANCE, SPRINT, AGILITY AND HEART RATE

SCHULZ, T.1, SCHNEIDER, R.1, OBERHOFFER, R.1

TECHNISCHE UNIVERSITÄT MÜNCHEN

INTRODUCTION:The positive influence of green exercise on health parameters has been scientifically described many times in recent years. (1). It has been shown to lower blood pressure, to improve mood and self-esteem, and to help restore attention. The comparison of physical stress indoors and outdoors also comes to these results. (2). Indoor and outdoor settings also influences perceived exertion during exercise. The question in the present study was therefore: is the maximum power of soccer players different in endurance, sprint and agility indoor and outdoor and how does this affect the physiological parameter heart rate?
METHODS: 10 active soccer players took part in the study (age 22.3±4,5yrs, BW 68.6±7.7kg, BL 177.0±8,4). All trained 2-3/week plus soccer games at weekends. The players were tested both indoor and outdoor within 14 days on condition (Cooper-Test), linear sprint (30m with interim times) and agility performance (agility sprint protocol after Rehagel). The Cooper-Tests were carried out indoor and outdoor on a measured tartan surface of 40x20m, the heart rates were measured with the Firstspeed Sports measuring system; the Fusionsport Smartspeed system was used for both linear sprint times and agility. The respondents were also asked about personal sensitivities, their motivation, willingness to perform and their assessment of their performance. Group differences in "indoor" "outdoor" were analyzed by T-test and correlation analysis via Pearson.
RESULTS: Participants reached in the Cooper-Test indoor 2568±254 m, outdoor 2556±219m. Average heart rate during the Cooper-Test was outdoor 174.7±10.8bpm, indoor 183.0±9.9bpm ($p=0.002$). The maximum heart rates achieved were 2.2 % lower outdoors ($p=0.034$), the minimum heart rates did not differ. Also the 3min recovery heart rates were equivalent. In the linear sprint test probands achieved 4.58±0.27sec indoor, 4.52±0.27sec outdoor. The agility tests were performed 7.1 % faster ($p=0.004$) outdoors (running around on the

right), while 3.1% better values were achieved on running around left (p=0.12). There is a highly significant negative correlation between the factor "weight" and "fun outdoor", a positive correlation for "age" and "sport in nature is more important to me than in a hall" or perceived "effort outdoor" and "motivation outdoor".
CONCLUSION: Particularly for the endurance range, there were discrepant differences between the achieved heart rate indoor and outdoor for the same mileage. Influences of the environment per se on heart rate and thus on the vegetative nervous system can therefore be confirmed, as they can also be found in the literature (3). The correlations show many different personal attitudes and physical conditions are influenced by the "Green Exercise" factor. This needs to be investigated in further studies.

SOCIAL SUPPORT FOR JAPANESE ATHLETES

KATAGAMI, E.
KYORITSU WOMENS UNIVERSITY

Social support has been acknowledged to contribute to an athletes physical and psychological health (Holt and Hoar, 2006), and reported as a salient resource for maintaining a healthy life as an athlete. In sport psychology field, social support for athletes is categorised to be 4 types: emotional (enhancing feelings of being cared for or loved), esteem (referring to competence or self-esteem), informational (providing the individual with advice or guidance), and tangible support (providing concrete instrumental assistance). Based on these dimensions of social support in sport, the effects of social support on athletes' psychological health has been examined (Katagami & Tsuchiya, 2017). Recently, social support research conducted in Japan revealed that athletes might experience various types of social support in addition to the existing categorised types of social support. Up to date, social support for athletes has been examined based on research conducted in Western countries. The aim of the current study was to explore types of social support considering Japanese sport context. After an approval was gained from the authors university ethics committee, voluntary research participants were recruited from two Japanese universities. Two hundred and thirty-four Japanese university students (Mage=20.62 ±1.90 years) who have experience as an competitive athlete were asked to fill in an open-ended questionnaire regarding social support in several contexts. The participants had played either individual sports (e.g. swimming, track and field, gymnastics, Judo, etc.), or team sports (e.g. football, basketball, lacrosse, baseball, etc.). All the 630 data gathered was read and reread by 2 sport psychology researchers and student whose major in sport psychology independently, then, categorised to gain agreement by all researchers. The results indicated that social support for athletes were classified into categories 9 types. For instance, it was shown that social support for injured athletes were creating supportive environment in a team, sense of belonging, and encouraging cognitive reconstruction. Social support for female athletes were categorized into several types including listening and sharing experience, spending time together, and giving advice. Further examination would be needed to conclude social support athletes in general.

BEHAVIORAL CHANGES IN TRANSGENIC MINIPIG CARRYING THE HUMAN APP MUTATION FOR ALZHEIMER'S DISEASE

OH, H.1, KIM, J.2, KIM, H.2, LEE, B.1
1: SEOUL NATIONAL UNIVERSITY , 2: OPTIPHARM CO. LTD.

INTRODUCTION:Alzheimer's disease (AD) is a fatal disease which animal models can potentially enable investigation of aetiology and treatment. In human AD patients, memory impairment is one of the most striking and consistent feature. The aim of the present study was to examine behavioral and memory test in the APP transgene expressed-AD minipig (APP-Pig).
METHODS: For scoring of behavioral changes of APP-Pig, behavior was observed on the basis of 14 items, and a score was given for each item to confirm the difference between APP-Pig and the control group (control). The behavioral observations of APP-Pig and normal minipig (control) were repeated 14 times during 1-4 years of age. We checked through periodic observation to detect changes in behavior according to age. The Memory function of APP-pig was checked by T-maze test to confirm the difference from that of control. The T-shaped road had two routes (the left and right arms, respectively) and a starting position at the front pouch. Food was placed at the left-arm-end at all time, and the right-arm-end was empty in the 1st test but the food placed on the 2nd test. The frequencies of touching the gate for exploring each route were recorded for 10 min. The time lap between two trials was 1 h. T-maze test was repeated four times (three replication per test) for four years. Statistical analysis of all data was performed using using GraphPad prism software.
RESULTS: The scores of behavioral changes of APP-Pig decreased significantly by age ($p < 0.05$). The results of evaluation showed twenty-five scores at 1 year, eleven scores at 2 years, seven scores at 3 years, and three scores at 4 years. In the control group, there was no change in behavior scores depending on age. In T-maze test, the control showed the higher frequencies of finding new food compared to APP-Pig, particularly the APP-Pig showed significantly lower spatial cognition than did the control ($p < 0.05$).
CONCLUSION: This study was demonstrated that APP transgene caused AD-like behavior symptoms in this porcine model. Being an age-dependent disease, the T-maze test should be repeated at older ages. This study was supported by #NRF-2016R1D1A1B03932198 and IPET (#311011-05-5-SB010).

Rehabilitation and (Sports)Physiotherapy

EFFECTS OF HIGH-SPEED POWER TRAINING ON NEUROMUSCULAR AND GAIT FUNCTIONS IN FRAIL ELDERLY WITH MILD COGNITIVE IMPAIRMENT DESPITE BLUNTED EXECUTIVE FUNCTION

SONG, W.

SEOUL NATIONAL UNIVERSITY

INTRODUCTION:Physical frailty and impaired executive function of the brain show similar pathophysiology. Both of these factors lead to dysfunction of neuromuscular and abilities in elderly. High-speed power training (HSPT) has been determined positive effects on neuromuscular function and gait performance, as well as executive function in the elderly. Thus, the purpose of this study was to investigate the positive effects of 8-week HSPT on neuromuscular function, gait and executive function in frail elderly with mild cognitive impairment (MCI).
METHODS: Forty-two physically frail elderly with MCI were randomly allocated to intervention and control groups (Intervention: n = 18 aged 73.77±4.64, weight 61.02±2.16; Control: n = 22 aged 74.22±4.46, weight 60.64±1.95). The intervention group was subjected to HSPT with an elastic band 3 times weekly for 8 weeks. Isometric contraction of knee extension and flexion with electromyography (EMG) was measured to determine the neuromuscular function. Parameters including isometric knee extensor strength, rate of torque development (RTD), movement time, pre-motor time, motor time, rate of EMG rise, and hamstrings antagonist co-activation were measured. Additionally, the 4.44-meter gait and timed up-and-go (TUG) test were administered to assess gait performance. A frontal assessment battery represented a variable of executive function.
RESULTS: The isometric knee extensor strength and RTD in the intervention group changed significantly from 1.13±0.08 to1.25±0.07, and 3.01±0.3 to 3.55±0.24, respectively, compared with the control group, which changed from 1.16±0.07 to 1.13±0.06 ($p<0.05$), and 2.99±0.27 to 2.85±0.21 ($p<0.05$), respectively. The movement time, motor time and rate of EMG rise in the intervention group were significantly changed from 921.69±40.10 to 799.51±72.84, 271.40±19.29 to 181.15±38.08, and 166.48±13.31 to 197.94±11.51 ($p<0.05$) compared with the control group, respectively. The 4.44-m gait speed and TUG in the intervention group decreased significantly from 6.39±0.25 to 5.5±0.24, and 11.05±0.53 to 9.17±0.43 ($p<0.05$) compared with the control group. However, the frontal assessment battery results remained essentially unchanged (11.38±2.56 to 12.16±1.79) in the intervention group compared with the scores of the control group (11.72±2.11 and 11.77±2.22).
CONCLUSION: Therefore, the findings of this study suggest the favorable effects of 8-week HSPT on the neuromuscular function and the gait performance in the frail elderly with MCI without increase in executive function.

AGE-RELATED CHANGES IN STRATEGIES USED TO AVOID OBSTACLES DURING A RESPONSE ION TASK

IKEZOE, T., YAGI, Y., ICHIHASHI, N.

GRADUATE SCHOOL OF MEDICINE, KYOTO UNIVERSITY

INTRODUCTION:In older adults, a decline in the ability to avoid obstacles may be implicated in higher incidences of trips and stumbles. Specifically, tripping over an obstacle while under attentionally demanding conditions is one of the most common causes of falls among older adults. However, there have been few studies focused on age-related changes in strategies used to avoid obstacles during attentionally demanding task. We investigated the effect of age on strategies used to avoid obstacles during different response selection tasks.
METHODS: Subjects included 29 community-dwelling older women (aged 72.5±7.2 years) and 10 young women (aged 21.4±1.7 years). Subjects were excluded if they had physical dysfunctions, which could influence measurements such as acute neurological and severe musculoskeletal and cognitive impairments.
Subjects performed a task of stepping over a 10 cm high obstacle as fast as possible in response to a visual cue during simple reaction (single-task) and choice reaction (selection-task) trials. The visual cue came from a light display placed at eye level, 5 m in front of the subject. During single-task trials only a blue light illuminated. During selection-task trials blue, red, and yellow lights illuminated randomly. In both single-task and selection-task trials, subjects were instructed to step over obstacles as fast as possible when the blue light illuminated. The strategies subjects used to avoid obstacles were studied using three measures: vertical clearance of the leading (swing) foot over the obstacle, vertical clearance of the trailing (stance) foot over the obstacle, and the landing distance of the leading foot in front of the obstacle.
Differences in measurement results between the young and older groups were assessed using unpaired t-tests or Mann-Whitney U tests. Paired t-tests were used to assess within-group differences between single-task and selection-task measurement results.
RESULTS: The older women had a significantly shorter landing distance of the leading foot than the young women, in both single-task and selection-task tests. Age-related differences were not observed in vertical clearances of either the leading or trailing foot.
When comparing differences between single-task and selection-task trials, there were no significant differences in vertical clearances of either the leading or trailing foot, nor in the landing distance of the leading foot in young women. Alternatively, in older women the vertical clearance of the leading foot increased and the landing distance decreased in selection-task compared to single-task trials.
CONCLUSION: We investigated age-related changes in strategies used to avoid obstacles. Our findings show that older women landed their leading foot closer to the obstacle after stepping over it compared to young women. Additionally, our results suggest that older women adopt strategies that include shorter stepping and increased vertical clearance when stepping over obstacles during response selection tasks.

UNANTICIPATED LANDINGS AS A POTENTIAL RE-INJURY RISK FACTOR: HOW LONG AFTER ACL RECONSTRUCTION AND RETURN TO SPORT DOES THE IMPAIRMENT PERSIST?

NIEDERER, D.1, GIESCHE, F.2, NIEMEYER, P.1, JANKO, M.3, STEIN, T.4, FRANK, J.3, VOGT, L.1, BANZER, W.2

1,2,3 GOETHE UNIVERSITY FRANKFURT/MAIN; 4 BGU FRANKFURT/MAIN

INTRODUCTION:Inadequate reactions to unforeseen external stimuli are regarded as a major cause for non-contact anterior cruciate ligament (ACL) injuries. We aimed to delineate a potential deficit in the ability to perform unanticipated jump-landing manoeuvres after ACL-reconstruction.

METHODS: Physically active adults with a history of unilateral ACL rupture and subsequent reconstruction (6 months to 7 years ago), cleared for return to sports (RTS), were included. All participants performed counter-movement jumps with unanticipated single leg landings. Visual information, shown at take-off, indicated the required landing leg. Jumping time [s] and successfulness [yes/no], vertical peak ground reaction forces at landing [N], as well as time to stabilisation after landing [s] and path length of the centre of pressure (CoP, [mm]) were calculated. Limb symmetry indexes (LSI) as common RTS outcomes were analysed for their association with the time since surgery.
RESULTS: Time since ACL reconstruction was logarithmically (basis 10) associated with side symmetry improvements in peak ground reaction force ($R2 = .23$, $p < .01$) and time to stabilization ($R2 = .18$, $p < .01$) during and after landing in unanticipated/unpredictable single-leg jump landing tasks. The asymmetry found persists up to 18 - 26 month post-surgery.
CONCLUSION: A deficit in unanticipated jump-landing ability seems to persist far beyond surgical restoration of mechanical stability and resumption of initial physical activities levels. The assessment of the ability to suddenly adapt movements to unanticipated visual stimuli may be a relevant complementary component within current functional testing canon in monitoring therapy success and RTS testing.

THE EFFECT OF JOINT MOBILISATION TREATMENT DOSE ON DYNAMIC BALANCE IN THOSE WITH CHRONIC ANKLE INSTABILITY

HOLLAND, C.J., HUGHES, J.D., DE STE CROIX, M.B.A.

UNIVERSITY OF WORCESTER

INTRODUCTION:Talocrural joint-mobilisations improve postural control in those with chronic ankle instability (CAI) (1). However, the effects of different treatment durations over multiple sessions have not been investigated. The study aim was to examine the effect of varying treatment durations over three treatment sessions on dynamic postural control in those with CAI.
METHODS: 48 female athletes with unilateral CAI (22.8 ±4.8yrs) were randomly assigned to balanced treatment groups (30, 60 or 120 seconds) and received three anterior-to-posterior talocrural joint mobilisation treatments equally spaced over a 5-day period. Dynamic postural control was measured prior to and immediately following each treatment session using the anterior (ANT), posterolateral (PL) and posteromedial (PM) directions of the star excursion balance test (SEBT). The uninjured extremity was used as a control for all measurements.
RESULTS: Interaction effects between group and treatment session for each reach direction were evidenced ($p \leq 0.001$). ANT improved for all treatment durations when compared to their control for all sessions ($p \leq 0.001$) with effect sizes being 'huge' (≥2.0). Longer treatment sessions produced significantly greater ANT improvements than shorter durations ($p \leq 0.005$). In contrast, there was no improvement ($p \geq 0.05$) in PL or PM for any treatment group when compared to their control. However, both treated and control limb showed evidence of improvement after each session. The 30s group (PL) and the 60s (PM) did show improvements over their control following session 1 ($p \leq 0.05$). Improvements in PL and PM reach distances were superior in the longer treatment groups than shorter duration treatment groups ($p \leq 0.05$).
CONCLUSION: Anteroposterior talar joint mobilisations improve postural control in ANT, with longer treatment durations conferring greater increases. This can be attributed to the associated increases in dorsiflexion seen following joint mobilisations, with around 28% of the variance in ANT being credited to improvements in dorsiflexion (2). For PM and PL, longer treatments appear to produce greater results, although the benefit does not seem limited to only the treated limb. This suggests a central processing mechanism is at play through increases in afferent transmission (3). This adds clarity to the use of joint mobilisations in the treatment of CAI, although further investigation of the potential 'cross-over' effect is warranted.

PROGRESSIVE RESISTANCE TRAINING IN CEREBRAL PALSY: DETERMINING RESPONDERS FROM NON-RESPONDERS

THEIS, N., NOORKOIV, M., LAVELLE, G., RYAN, J.

UNIVERSITY OF GLOUCESTERSHIRE

INTRODUCTION:Although resistance training for adolescents with cerebral palsy (CP) is often advocated as a means of delaying the loss of mobility, reducing the risk of cardiovascular disease and improving walking function, not all individuals will benefit to the same extent. Discriminating clinical groups based on their expected responses to a resistance training intervention is important, to avoid prescribing demanding training programmes when no improvement can be expected. Therefore, the purpose of the study was to investigate whether responders to a resistance training programme could be discriminated from non-responders based on pretraining variables.
METHODS: Thirty participants with spastic CP (Age: 13.4 ± 2.7 y; Gross Motor Function Classification (GMFCS) I-III) were assessed before and after a 10-week progressive resistance training intervention targeting the plantarflexor muscles. During the intervention, participants completed 1 group session, and 2 home-based sessions each week. Based on strength changes from a control group (n = 31, age = 14.0 ± 2.8 y; GMFCS I-III) over the 10-week period; responders to the intervention were defined as having a >8% increase in muscle strength. With binary logistic regression, responders were distinguished from non-responders based on available baseline data. Compliance to the intervention as well as functional variables: gross motor function and average daily step count (measured over 7 days by accelerometery), and biomechanical variables: medial gastrocnemius muscle activation (measured at rest and during a maximal contraction with electromyography), ankle range of motion, ankle and knee joint power, (measured during walking using 3D motion analysis and an instrumented treadmill) and muscle volume (measured with 3D ultrasound), were included in the analysis.
RESULTS: After the 10-week intervention, 57% of participants met the criteria for responders. In the responder group, maximal strength increased significantly by 71 ± 59% ($p = 0.020$), whilst non-responders showed a -13 ± 19% change, which was not significantly different from baseline ($p = 0.064$). Interestingly, a binary logistic regression model containing medial gastrocnemius muscle activity and knee power was found to discriminate between responders and non-responders, correctly predicting 82.4% of responders and 84.6% of non-responders. All other variables were shown to be poor predictors of response to progressive resistance training in this population.
CONCLUSION: Those with cerebral palsy who have higher levels of pretraining medial gastrocnemius muscle activity, coupled with low knee joint power, are more likely to improve with progressive resistance training. This information may help clinicians to make informed decisions about those individuals with cerebral palsy who would be most likely to benefit from progressive resistance exercise.

THE CHARACTERISTICS OF BONE METABOLIC MARKERS TO STRESS FRACTURE PREVENTION AND EARLY DETECTION BY LONGITUDINAL STUDY IN COLLEGIATE MALE LONG DISTANCE RUNNERS

FUJITA, S., SAKURABA, S., KUBOTA, A., KISHIMOTO, K., WAKAMATSU, K.

J.F.OBERLIN UNIVERSITY

INTRODUCTION:Stress fracture is a break in bone tissue caused by repeated minor mechanical stress caused by activities such as running, and it can lead to a complete fracture. Stress fracture is a serious injury as it takes a long time to completely heal and prevents athletes from training. Based on previous studies, TRACP-5b (bone resorption marker) increases with a history of stress fracture, but it may not be related to the onset of stress fracture [1], whereas urine-NTX (bone resorption marker) increases when stress fracture develops [2]. Reactions to stress fractures may be characterized by increased bone resorption markers. To clarify the characteristics of bone resorption markers, further investigation is necessary. We aimed to investigate the characteristics of bone metabolic markers for preventing and early detection of stress fracture by longitudinal study in collegiate male long distance runners.
METHODS: The participants were 29 male long distance runners (18 to 22 years old) who belonged to college from 2011 to 2014. BAP as bone formation marker, TRACP-5b and urine-NTX as bone resorption marker were measured to monitor bone metabolism. Participants who were measured at least three times were used for analysis. A mean value of measurements without stress fracture of each participant was calculated and used as a normal value. 3 participants who developed stress fracture during the measurement period were excluded from the analysis. Comparison was made between participants with and without history of stress fracture. Five participants had a history of stress fracture (SF group) and the remaining 21 participants had no history of stress fracture (Control group).
RESULTS: The normal value of TRACP-5b was significantly higher in SF group (620.1±88.9 mU / dL) than in control group (501.7±94.8 mU/dL, $p<0.05$). There was no significant difference in BAP between SF group (19.4±3.4μg/L) and CON group (18.5±4.5μg/L). In addition, There was no significant difference in urine-NTX between SF group (66.7±23.9 nmolBCE/CRE) and CON group (57.8±16.5 nmolBCE/CRE). Three participants developed stress fractures. Only NTX increased during stress fracture in 2 of 3 participants. BAP, TRACP-5b did not change when developing stress fracture.
CONCLUSION: Male long-distance runners who had a history of stress fracture were shown to have a high value of TRACP-5b. In addition, the high value of NTX showed the possibility of developing stress fracture.

JUMPING ABILITIES IN PATIENTS AFTER LIVER TRANSPLANTATION SURGERY

BUSKO, K., SKLADANÝ, L., SZULC, A., RÁC, M., ADAMCOVÁ-SELCANOVÁ, S., BADINKOVÁ, J., PILECKI, O., GÖRNER, K.

KAZIMIERZ WIELKI UNIVERSITY

INTRODUCTION:Liver transplantation surgery saves patients from premature death and provides patients with a chance to return to an active life. With properly selected physical activity, transplant recipients can obtain results comparable to healthy individuals at a similar age (1). The aim of the study was to investigate changes of maximal power of the lower extremities and height of jump measured in akimbo counter-movement jump and counter-movement jump in patients after liver transplantation surgery during one years.
METHODS: Five patients one year after liver transplantation surgery (age 50.5 ± 16.9 years, body mass 76.3 ± 15.0 kg, body height 166.0 ± 7.0 cm, BMI 27.58±4.28) took part in this study. The total physical activity of patients after liver transplantation surgery was determined according to the IPAQ (2). The activity level of the patients was compared with MET-min/week measure in the IPAQ classification. Power of lower extremities and the height of the rise of the body mass centre (COM) during vertical jumps were measured using a force plate (3). Each participant performed three akimbo counter-movement jumps (ACMJs) and three counter-movement jumps (CMJs). Two measurements were carried out: one year after liver transplantation surgery (I), two years after liver transplantation surgery (II). The analysis of variance (ANOVA) for repeated measures was used to compare the study results. The significance of differences between means was evaluated post hoc with the Scheffé test (STATISTICA v. 13.0, StatSoft, USA).
RESULTS: Total physical activity per week as measured by IPAQ was 3851.2±2450.4 MET-min/week in the patients. The values of ACMJ height of jump insignificant increase from 0.158±0.021 m after one year after liver transplantation surgery (I) to 0.161±0.023 m after two years after liver transplant (II) while the relative maximal power were 23.12±3.04 W/kg, 24.89±5.87 W/kg, respectively. The maximal power were 1768.2±431.2 W (I) and 1921.8±635.0 W (II) in ACMJ. The height of CMJ jump were 0.187±0.028 m and 0.208±0.050 m, respectively. The maximal power were 2143.6±618.1 W (I) and 2262.0±653.6 W (II) in CMJ. The relative maximal power values of CMJ changed insignificantly from 27.82±5.36 W/kg (I) to 29.54±6.95 W/kg (II).
CONCLUSION: It has been described that after receiving a donor organ the patients reported improved quality of life and were frequently able to successfully return to employment (1). The main finding of the study is that the maximal power and height of a jump in the ACMJ and CMJ insignificant increased in the patients after liver transplantation during one year.

EFFECTS OF A SELF-REGULATED ISOMETRIC HAND-GRIP EXERCISE PROTOCOL ON PRESSURE PAIN

WADE, A.

UNIVERSITY OF GREENWICH

INTRODUCTION:Using the CR-10 Scale to regulate isometric handgrip exercise (IHGE) has shown that a CR-10 level '6' produces an average of ~33% maximal voluntary contraction (MVC) over a 120s contraction (1). Low-intensity isometric exercise has been shown to produce the greatest analgesic effect (AE) in healthy participants (2). The aims are two-fold:
(i) to determine whether completing a self-regulated IHGE protocol (CR-10 Level '6') produced %MVC forces equivalent to approximately 30%MVC.
(ii) to determine whether this 4 x 120s of self-regulated IHGE produces an AE, in either the ipsi- or contra-lateral hand, in response to experimental pressure pain.

METHODS: Twenty-six (Female=11; Male=15) healthy participants completed: (i) 120s IHGE with visual feedback at 30%MVC (assessment trial; AT) and (ii) On 3 different days, 4 x 120s of self-regulated IHGE at CR-10 Level 6 (consistency trials; CT). Participants completed 120s of IHGE for the AT during which %MVC (N) was recorded. During the repeated IHGE (CT) trials, participants had their %MVC force recorded. To assess the AE of the IHGE, the participants were asked to complete a pressure pain threshold (PPT) and supra-threshold pain rating (S-TPR) test, before and after each of the 4 x 120s of self-regulated IHGE on performed on 3 different days. The pressure pain tests were completed on the ipsilateral, followed by contralateral, hand.
RESULTS: The AT showed that there was no significant change in force over the 120s ($p>.05$) and it was equivalent to a mean of 29%MVC. Subsequently, the %MVC force that was recorded during the 3 CTs, declined with each additional 120s period of exercise ($p<.05$), exhibiting a similar declining force trend.
There was a significant AE in the ipsilateral hand, after the self-regulated IHGE, but only for CT2 (PPT test, Pre: 375±195; Post: 424±196 kPa; $p<.05$). No significant AE was observed for CT1 or CT3 on the ipsilateral hand. On the contralateral hand, both the CT1 (Pre: 329±171; Post: 370±188 kPa, $p<.05$) and CT2 (Pre: 346±188; Post: 393±204 kPa, $p<.05$) showed a significant increase in PPT scores. For S-TPR there was a significant increase in pain rating after CT2 on the ipsilateral hand, but no changes observed after any other CT.
CONCLUSION: This study showed that it is possible to reproducibly induce a sizeable AE (of approximately 12%) after repeated sessions of 4 x 120s of self-regulated IHGE. The findings suggest that it is possible to induce an AE in both ipsi- and contralateral hands. The ability to induce this effect whilst using a self-regulated exercise protocol (at CR-10 of '6') suggests that it may be possible to perform this kind of exercise easily at home, without any expensive equipment.

ARTIFICIAL CO2-WATER BATHING FACILITATES RECOVERY FROM MUSCLE HARDNESS IN FATIGUE CAUSED BY HIGH INTENSITY ANAEROBIC EXERCISE

YAMAMOTO, N.1, TAKENOYA, F.2, WADA, T.3, HASHIMOTO, M.4
1JAPANESE RED CROSS HOKKAIDO COLLEGE OF NURSING, 2HOSHI UNIV., 3KOKUSHIKAN UNIV., 4TEIKYO. UNIV. SCI.

INTRODUCTION:Facilitation of the blood supply to the muscle and of oxygen consumption in the muscle by a local immersion of the extremities into high concentration carbon dioxide water (CO2-water, CO2≥1000ppm) (Yamamoto, 2007), suggests an improvement of muscle performance and flexibility. In the present study, we investigated whether the whole body bath into artificially made high concentration CO2-water (CO2≥1000 ppm) influences recovery of muscle hardness in fatigue after high intensity anaerobic exercise.
METHODS: The healthy male college students (n=6, 18-21yrs, 171.3±6.7cm, 73.6±13.0kg) participated in this study. The cycle ergometer work tests lasting 30 seconds were used to estimate anaerobic power with leg pedaling exercises. Exercise loads of the tests were 0.075kp per body weight. Anaerobic power was determined by measuring the highest power output during 30 seconds. Core temperature (CoreT) and ECG were recorded continuously throughout the experiment. The subjects performed 30-s maximal pedaling exercise, and took bath in tap- or CO2-water at 35 °C for 10 minute after exercise. Subjective thermal sensation (TS) in the body bath was also recorded. Vastus lateralis (VL) dominant muscle hardness was evaluated using the elastography. Evaluation of blood lactate (BLa) and visual analog scale of muscle (VAS) were performed at pre- and immediately after-exercise, and at 10 min after exercise.
RESULTS: The strain ratio (SR) between the VL and a reference material was calculated. TS in the CO2-water was significantly higher than in the tap-water (tap-water vs. CO2-water, -0.17±0.76 vs. 1.17±0.41, $p<0.01$). At 10 min in recovery, in the CO2-water compared with the tap-water, SR significantly decreased quicker (0.49±0.25 vs. 0.91±0.25, $p<0.01$). CoeT, VAS and BLa tended to be lower in CO2-water than tap-water, but no significant difference was observed.
CONCLUSION: We reported previously that the muscle blood flow in the immersed part was larger in CO2-water than tap-water of a same temperature. In addition to a local effect of CO2, suppression of muscular sympathetic activity may also contribute to the increase in local blood flow. Facilitation of muscle hardness recovery shown in this study might be caused by the increased muscle blood flow. The present results suggested that CO2-water bath may contribute to rapid recovery from the muscular hardness induced by high intensity exercise.

MUSCLE ACTIVITY OF LOWER EXTREMITIES AND THE TRUNK WHILE DOING UNILATERAL SQUATS WITH VIPR

IZUMI, S., SHIRAKAWA, K., TAGUCHI, N., KASUGAI, Y.
HOSEI UNIVERSITY

INTRODUCTION:The trunk muscle activity of bilateral squat using ViPR has been reported (Izumi S. et al, 2016). The purpose of this study was to evaluate muscle activities of the lower extremities and the trunk while performing unilateral squats using ViPR.
METHODS: Seventeen collegiate students (men=8, women=9, age=20.7±0.7 y) participated in this study. All subjects underwent right leg (unilateral) squats using ViPR. ViPR is a 4-kg pipe-shaped weight (diameter, 14 cm; length, 107 cm). Muscle activities were measured during normal squats (1. Normal) and four types of squats using ViPR (2. holding ViPR on the head: Head, 3. holding ViPR in front of the thigh: Front, 4. Holding ViPR at the right side of the body: Right, 5. Holding ViPR at the left side of the body: Left). Surface electromyography (SX230, Biometrics Co.) was used to assess muscle activity. The electrode was attached to the rectus abdominis, external oblique, internal oblique, multifidus, gluteus maximus, gluteus medius, rectus femoris, and biceps femoris. All the electrodes were attached on the right side. The section targeted for analysis was 0.4 s when the subject flexed his/her knee, and the thigh was parallel to the ground. The root-mean-square was calculated and normalized to the % maximal voluntary isometric contractions (MVC) from each squat. Subjects attempted to elicit MVC for each muscle. One-way ANOVA and multiple comparisons with Bonferroni method were used for statistical analysis.
RESULTS: The rectus femoris muscle was the most intense activity in all trials. The gluteus maximus was secondly intensely contracted muscle in all trials. The internal oblique muscle had the most intense activity (48.9%) on the Right and was significantly different when compared with Normal ($p<.05$). The multifidus muscle had the most intense activity (70.7%) on the Left, and was significantly different from that in Normal (48.2%) and Front (52.4%, $p<.01$).
CONCLUSION: The trunk muscles and muscle activities of the lower extremities were more intense in single leg squat than in both legs squats. Especially the muscle activity of the rectus femoris muscle and gluteus maximus muscle on the standing side was intense. In the trunk muscles, the muscle activity was the most intense when the internal oblique muscle was on the Right and the multifidus muscle was on the Left.

THE INFLUENCE OF DYNAMIC TAPING ON LANDING STRATEGY FROM PLATFORM IN ATHLETES WITH ANKLE INSTABILITY

LEE, H.J.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION:Lateral ankle sprains (LAS) have high prevalence in sport injuries, and 40 percent of people with LAS will develop chronic ankle instability (CAI). Most of them seek rehabilitation programs to enhance their recovery and performance. Some of them still need external support to maintain ankle stability during activities. Dynamic tape is one of elastic tapes with 4-way stretching and strong recoil force which can absorb mechanical load and improve movement pattern. Is it possible to improve muscular activation after dynamic taping on CAI? The purpose of this study was to compare the neuromuscular control in CAI with and without dynamic taping during single leg drop landing.
METHODS: Fourteen chronic ankle instability participants with regular exercise habits were enrolled in our study. Participants were asked to perform single leg drop landing from 40cm platform with and without dynamic taping. The kinematic and kinetic data were collected by Vicon 3D motion analysis system (250 Hz), Kislter force plate (2000Hz) and Delsys surface EMG (2000Hz). These data were synchronized by using Nexus motion capture software. Paired sample t-test was used to analyze the statistical difference with alpha level of .05.
RESULTS: The results showed that the ankle inversion angle and eversion angular velocity were significantly greater with dynamic taping in the moment of landing ($p < .05$). The maximum eccentric power of plantar flexors was significantly decreased than pre-tape in the descending period ($p < .05$) and the muscular activation of peroneus longus were also decreased in the landing period ($p < .05$). However, there was no difference in the peak vertical ground reaction force and time to peak vertical ground reaction force.
CONCLUSION: Dynamic taping can efficiently improve the shock absorption of ankle joint when landing. It can be another choice of ankle taping for chronic ankle instability in the future.

THE INFLUENCE OF SELF PELVIC TRACTION ON TRUNK FLEXIBILITY AND SPINAL ALIGNMENT

KUDO, H., SAKAI, R.

MEJIRO UNIVERSITY

INTRODUCTION:Low back pain is one of the most common disorder regardless of race, sex, age, and a pelvic traction is one of its popular treatments.
In recent years, a pelvic traction device to be carried out by himself has been developed, which is called Self Pelvic Traction. The purpose of this study is to verify the effect of the Self Pelvic Traction.
METHODS: This study comprised 40 healthy volunteers (20 male, 20 female), average aged 21y.
Alignment (sternum angle, lumbar vertebra angle, sacral tilt angle) of standing position and trunk flexion in standing position, and Finger Floor Distance (FFD) were measured before and after Self Pelvic Traction and conventional electric traction, and compared them.
RESULTS: The FFD and the sacral tilt angle increased in both Self Pelvic Traction and conventional electric traction. Although the pelvic tilt (sacral tilt angle) in the standing position increased after the conventional electric traction, decreased after the Self Pelvic Traction and the pelvis stood upright.
CONCLUSION: From the results of this study, it was suggested that the Self Pelvic Traction, similar to conventional electric traction, showed effects on spinal alignment and trunk mobility, and could be one of the promising method to self-care for the back condition. Although we performed static analysis in this study, but it seems that dynamic analysis and field research are necessary from now on.

AN ANALYSIS OF SLEEP AFTER ARTIFICIAL CO2-WATER IMMERSION IN COLLEGE ELITE SWIMMER

WADA, T.1, YAMAMOTO, N.2, SHINTAKU, Y.3

1 KOKUSHIKAN UNIVERSITY, 2 JAPANESE RED CROSS HOKKAIDO COLLEGE OF NURSING, 3 OSAKA UNIVERSITY OF ECONOMICS

INTRODUCTION:The bathing and sleep processes in physical recovery play an important role in human. Sleep is homeostatically controlled and, after a prolonged period of stress, we recognize importance of the sleep. Exercise load results in an increase in sleep, indicating that sleep is tightly maintained at a restricted level. The purpose of this study is to examine the physical recovery by sleep after artificial CO2-water immersion in college elite swimmer.
METHODS: Eight healthy college elite swimmer participated in this study. The subjects were taken two different types of bathing; tap-water bathing and CO2-water bathing. The water temperature of both bathing was 38 degrees Celsius. The subjects were attached to surface electrodes on their forehead to record an EEG (EEG sensor ZA, Proassist, Japan). To measure the sleep-wake cycle, accelerometers (Lifecorder GS, SUZUKEN, Japan) was used. The sleep-wake data were analyzed by circadian rhythm analysis software (SleepSign Act, KISSEI COMTEC, Japan). SpO2 and body movement and pulse were measured by means of near-infrared spectroscopy (PulseWatch PMP-200, Pacific Medico, Japan). Sleep variables analyzed time in bed (TIB), sleep period time (SPT), total sleep time (TST), wake time after sleep onset (WASO), sleep efficiency (SE), sleep latency (SL), time of sleep onset, time of wake onset, and bed out latency (BOL).
RESULTS: SL was significantly shorter in CO2-water bathing than that in tap-water bathing (7.8±2.3 min vs 16.5±3.8 min $p<0.05$). SE was significantly higher in CO2-water bathing than that in tap-water bathing (90.3±3.5% vs 83.2±4.6%, $p<0.05$). During sleep of the single night, the delta wave incidence of EEG appeared more in the sleep after CO2-water bathing. Therefore, these results suggest that as CO2-water bathing could raise body core temperature enough, this hyperthermia may cause a deep sleep.
CONCLUSION: Sleep is homeostatically controlled, and indeed, an increase in the NREM sleep is typically observed after CO2-water bathing in comparison to tap-water bathing. The sleep after the CO2-water bathing seems to be extremely useful in the physical recovery from fatigue.

PATIENTS WITH CONTRALATERAL ANTERIOR CRUCIATE LIGAMENT INJURY SHOW GREATER INTERNAL ROTATIONAL LAXITY OF KNEE

MASEGI, S., MIYAKAWA, S.
UNIVERSITY OF TSUKUBA

INTRODUCTION:Rotational knee laxity is known as an intrinsic risk factor for anterior cruciate ligament (ACL) injury. However, there was no convenient way to measure rotational range of motion. To this end, we developed the RotorMeter, a simple and non-invasive external device intended to measure rotational range of motion of the knee, which we reported to be reliable and valid at the ECSS2017 Annual Meeting. The purpose of this study is to use the RotorMeter to determine whether rotational range of motion of knee characteristics differ between non-injured knees in groups of both healthy volunteers and patients with a previous contralateral ACL injury.
METHODS: A total of 13 women with a previous contralateral ACL injury and 13 healthy women participated in the study. Patients were tested using the Rotormeter, the original knee rotation measurement device. Torque of 5.0 Nm and 90° angles of knee and hip flexion were used to measure the range of motion both internal and external rotation and total (internal + external) knee rotation was calculated. Only the normal (non-operated) knee data were used for this study. And the general joint laxity test was examined. Students t-tests was used for statistical analysis by SPSS® software.
RESULTS: Compered to healthy volunteers, patients with a contralateral ACL injury demonstrated significantly greater knee internal rotation (37.8 ± 6.13° vs. 31.1 ± 6.16°, P=0.016) and the general joint laxity test score (4.3 ± 1.43 vs. 2.7 ±1.39, P=0.009). But there were no significantly differences in knee external rotation (50.6 ± 10.96° vs. 50.8 ± 8.52°, P=0.966) and total knee rotation (88.4 ± 14.41° vs. 82.1 ± 12.71°, P=0.265).
CONCLUSION: We could find that patients with a contralateral ACL injury has greater knee internal rotational range of motion and the general joint laxity. These results support the present study (Branch et al, 2010). It was suggested that knee internal rotational range of motion has potential as ACL injury risk screening factor.

CHINAS SPORT INDUSTRY POLICY UNDER XI JINPINGS REGIME:FROM ASPECT OF THE GOVERNMENT

TAN, T.C.
NATIONAL TAIWAN NORMAL UNIVERSITY

Having become the second largest economy, China is now striving to increase the power it holds over the global economy and culture, hoping that its 'Chinese Dream' of becoming a world power could be reached. Under Xi Jinping's regime, the State Council of the Peoples Republic of China announced that the gross domestic product (GDP) of sport industry should be increased over than 5 trillion RMB by the year of 2025. Besides, each local government was also requested to reach a certain amount of output value for sport industry. This phenomenon of dominating the development of sport industry through the power of state is indeed rarely seen over the world. For this research, two years were taken for the researcher to have a thorough investigation and deep understanding of the development of sport industry in China through a macro perspective. Content analysis is conducted for data collected by semi-structural interviews with representatives from the government and private sectors. Policy Change Theory and Elite theory were used for shaping the theoretical framework for this research, which aims at investigating the Chinese government's policy change for sports industry under Xi Jinping's regime, along with the purpose behind. This research adopted the five policy change indicators (including organization, statutes, budget, personnel, and media) developed by Hogwood and Peters (1983) and Zhuang (2003), hoping to help us assess the extent of China's sports industry change. Furthermore, Elite Theory was adopted as our analytical framework for explaining how the political elites tackled the difficulties in sports industry in China. Finally, the presentation of our findings would be divided into three parts, as follow: driving forces behind the policy change, policy change reflected in the five dimensions and conclusion.
Keywords: Chinese Dream, World Sports Power, Political Elites, Policy Change, State Capitalism

CHANGES IN COMPOSITION OF EXERCISES OF THE RINGS IN MEN'S' ARTISTIC GYMNASTICS

DAISUKE, K.
TOKYO GAKUGEI GRADUETE SCHOOL

Introduction
In the 2017 version the FIG Code of Points for Men, more than 120 elements on the rings were introduced. However, currently, fewer types of elements on the rings are performed. The purpose of this research is to gather elements from the compositions of exercises on the rings from 2008 to 2018 for each element and to clarify future trends of the composition of exercises that can be conceived from these results.
Methods
The analysis target was 80 exercises of gymnasts who advanced to the World Championships and the Olympic Rings apparatus finals from 2008 to 2018. The composition of exercises of each gymnasts were gathered for each elements from "Kennkyu buho" published by the Japanese Gymnastics Association and used as the basic material of this research. Based on the data, we conducted comparative consideration from the viewpoint of each group and change of code of points.
Results
Currently, elements of Rings are divided into four groups of "Kip and swing elements & swings through or to handstand", "Strength elements and hold elements", "Swing to Strength hold elements", "Dismounts". In Swing elements, 2017 version code of points, elements above the E difficulty is only ONeill. ONeill has not been performed only four times in the last 10 years. In Swing to handstand elements, either "Swing forward. with straight arms to handstand" or "Uprise backward. or giant swing to handstand with straight arms" is being performed. In swing to hold elements, there are many performed of "support scale at ring height" and "support scale" elements. There is "Back kip to support scale" in the elements that has been performed more than E difficulty in recent years. There were gymnasts to performed this elements from 2008 to 2011, however there were 0 number of performed elements from 2013 to 2016. This elements was performed twice each year in 2017 and 2018. "Strength elements and hold elements" has a lot of high-level elements. Therefore although there are many choices of elements. In the dismount, "Double salto backward. stretched with 3/2 or 2/1 twist." was not performed in the apparatus finals using 2009 code of points. However the apparatus finals using 2017 version code of points were performed 1 or 2 people.

Discussion
The trend of elements performed has changed greatly with the changes in the Code of Points. it is highly likely that the mumber of elements to be performed will decrease.

THE DEVELOPMENT HISTORY AND INVESTIGATION OF CHINESE TRADITIONAL SPORTS "YOUNGER" DANCE

ZHAO, Y., ZHENG, H.S.

GUANGZHOU UNIVERSITY

The development history and investigation of Chinese traditional folk sports "Younger" dance
Zhao Ying, Zhen Hanshan.
Department of Physical Education and Sports Science in Guangzhou University
Introduction
The traditional Chinese folk dance "Younger" is a unique self-amusement sport's activity in China .It has been a intangible culture heritage over a history of more than 100 years , which includes singing , dancing, drama ,martial arts ,juggling and so on .Dance ,as a inalienable form of physical activity ,can positively improve human health . In ancient times, the transformation of "Younger" dance as a spiritual force can boost morale, which successfully demonstrated the times and styles of the peoples physical self-improvement . Therefore , the research of "Younger" dance has a positive benefit on promoting traditional sport culture prosperity and broaden the development of sport for all.Based on the study of current development of Younger dance culture ,this paper aim at exploring the historical origins towards the changes of Younger dance ,and try to discover the influence of social development of "Younger" dance under different historical conditions for the purpose to provide a constructive suggestion for the development of traditional Chinese folk sport"Younger" dance.
Methods
a)literature data method to discover the development of original and performing forms of Younger dance respectively ; b)The field survey method is used to conduct in-depth investigation on the specific expression forms of Younger ; c)The interview method is used to interview 200 performers of Younger to deeper understand the types ,footwork ,costumes and musical instruments of Younger dance.
Results
a)Chinese traditional sports "Younger" dance is a realistic life map under different historical geographical background , which is the most direct reflection of the people's spiritual outlook and behavioral dynamics ; b) It originated form the peasant -labor singing and dancing ,which symbolize the human worship of the sun ; c) With the combination of traditional songs and dramas to functional performances with characters, stories, and narratives ,the plot connotation not only has distinct national characteristics , but also has a greater effect on revitalizing the regional economy and improving the national fitness ; d) The Younger cultural influence gradually declined and the cultural connotation of the story content was isolated from public people .Hence, the Chinese traditional sports "Younger" dance was on the verge of disappearing .
Discussion
As time goes by, the Younger culture has changed constantly, which inevitably result in a phenomenon of cultural vacancy . Therefore, we should take the essence and discard the dregs of "Younger" dance culture for the purpose to improve "Younger" dance culture modernized , qualified and internationalized to improve the Chinese traditional sports the "Younger "Dance.

WHAT IS UNIVERSITY PHYSICAL EDUCATION IN JAPAN? : POSSIBILITY OF UNIVERSITY PHYSICAL EDUCATION

MORITA, H.

CHIBA INSTITUTE OF TECHNOLOGY

Introduction
At present, there are about 780 universities/colleges in Japan, and about 98% of them include P.E.(Physical Education) as part of degree requirements regardless of one's major. P.E. here means physical education classes whose students' major is not physical education or sport, for example, engineering, literature, etc.
Methods
Looking back on the history of university physical education in Japan, philosophically consider the essence of physical education at university.
Results and discussion
Is P.E. necessary in university? If so, what should its purpose and contents be?
In Japan, the new university system (the post-war new education system) was introduced in 1949 and in order to improve health conditions of youth at that time, especially to strengthen their physical endurance and prevent T.B. (tuberculosis), P.E. was introduced under the guidance of GHQ with 4 compulsory credits.
The regulation stating 4 compulsory credits was amended in 1991 and since then, each university has been given discretions whether to make students take P.E. or not, and if so, how many credits they have to obtain.
Currently, various purposes and contents of university physical education are offered, but many of them are the same as those in schools up to high schools, such as "education for health", "improving physical strength" and/or "motivation for lifelong sports", and there is a tendency to accept it if it guarantees opportunities for exercise.
However, is there not a risk of university physical education being scaled down in this way?
It will be necessary for university physical education to implement something different from extra-curricular activities in high school or sports activities outside university which students can only experience in university physical education.
The purpose of this research is to construct "harmony" and "science" based upon new sensibility (physical body) which replaces modern knowledge and sciences centred around reasons (brain), through physical activities.
This is where the possibility of Japanese university physical education must lie.
Deadlocks of the Great East Japan Earthquake or liberalism (capitalist economy) indicate the limitations of modern knowledge and sciences.
This research intends to examine that university physical education is where students learn to "feel what their body actually feels" and "feel what they feel with other people".

CHANGES IN PHYSICAL ACTIVITY OF CHINESE ADULTS - BASED ON DATA FROM 2014 AND 2010 PHYSICAL ACTIVITY SURVEYS

CHEN, X.

BEIJING INSTITUTE OF SPORTS SCIENCE

Introduction
Based on the survey data of physical activity of adults aged 20-69 years since 2010, the total number of qualified questionnaires was 352,411, of which 179,989 were in 2010 (89,994 males and 89,995 females), and 172,422 in 2014 (85,888 males and 86,634 women). Through five years of changes in physical activity of Chinese adults, it is possible to observe the dynamic changes of physical activity in adults, provide data for the study of physical activity, provide a policy basis for the development of guidance on physical activity.
Methods
The international physical activity questionnaire (long volume) was used and the survey was carried out in China after being verified by reliability and validity. Investigators were trained and qualified to conduct face-to-face surveys. SPSS18.0 software was used to assign and summarize various physical activities according to the standard, and the percentage was calculated for the categorical variables. The chi-square test was used to compare and $p<0.05$ was taken as the significant difference value.
results and discussion
The level of traffic-type physical activity in Chinese adult has a very significant change, $p<0.001$, and the overall level tends to be active . The proportion of male adults in the total meditation group decreased by 32.7%, the inactive group increased by 35.4%, and the activeness group decreased by 2.7%. The three groups of female adults fell by 41.9%, rise by 44.9% and fell by 3%.
Work styles Physical activity levels are divided into four categories: complete sit-up, inactive, moderately active, and highly active. The physical activity of adult working styles in China has a very significant change, $p<0.01$, and the level of physical activity in working mode tends to be static (bad). The four groups of male increased by 16.2%, 0.9% and decreased by 9.5% and 7.6% respectively; the female four groups increased by 12.6%, 0.6% and decreased by 7.5% and 5.7% respectively.
The changes in physical activity of domestic workers in China have a very significant difference ($p<0.01$). The three(complete sit-in, inactive, and moderately active) groups of man were reduced by 0.4%, 1.6% and increase by 2.1% respectively. The three groups of women fell by 1.2%, 0.4% and rise by 1.6% respectively.
Chinese adults have had a very significant change, $p<0.01$, and the proportion of participating in physical exercise in leisure time has risen sharply and tend to be active. The four groups(full sit-in, inactive, moderately active, and highly active)of male decreased by 31.4% and increased by 25.6%, 2.4% and 3.4% respectively. The female has decreased by 36.6%, increased by 28%, 4.6% and 3.9% respectively. In leisure time, the occasional exercise rate of Chinese adults has increased by 11.8%, the regular exercise rate increased by 9.7%, and the non-exercise rate decreased Significantly ($p<0.01$).

POPULARIZATION AND PROMOTION OF THE GAME OF GO IN EUROPEAN AND AMERICAN COUNTRIES

DENG, Y., ZHAO, W., SUN, Q.

SHANGHAI JIAO TONG UNIVERSITY

Introduction
As an ancient oriental board game, Go is very popular in East Asia. On the contrary, in European and American countries, the popularity of Go has always been at a very low level. AlphaGo, a computer program developed by Google DeepMind (Silver 2016, 2017) defeated Lee Se-dol and Ke Jie respectively, which attracted wide attention in western countries. Why is it so difficult to popularize the game of Go? Why can this competition cause so much concern among people who even have not heard of Go before?
Methods
This paper analyzes the reasons why the game of Go is so difficult to be popularized in Europe and the USA, and how Google company successfully breaks the deadlock. Material from media coverage and previous research will be studied from the perspective of sports sociology.
Results and discussion
The cultural differences between Western and Eastern societies and their resulting differentiation in the value of sports partly explain why the game of Go is unpopular in Europe and the United States. For thousands of years, the prevalence of Confucian culture in East Asia has greatly influenced peoples pursuit of the intrinsic value of sports in this region, while westerners who are deeply influenced by the Olympic spirit pay more attention to the shaping of peoples external image and power through sports activities (Lu 2009). In addition to the lack of physical activity, the game of Go is less enjoyable to watch. Viewers must reach a certain level before feeling the charm of Go game, which also makes the population of Go limited. Meanwhile, this problem has undermined the healthy collaboration between sports and sponsorship, emptying Go clubs and deterring sponsors. The low media attention on Go game has further deprived Westerners of access to it. Go terminology is another difficulty for that most English Go terms are derived from Japanese (Beheim 2014, Nam 2004). In fact, most westerners who show interest in the game of Go are curious about the game theory, mathematics, calculation and other problems reflected in it. By launching a Go game between humans and computer programs, Google has applied a series of marketing strategies to enhance its high-tech brand image in mass media and brings Go into the mainstream of European and American society. At present, the promotion of Go mostly relies on the corporate sponsorship and fewer volunteers, but this is by no means a long-term solution. It's necessary for Go associations in charge to establish more practical and mandatory plans.

A STRUCTURAL EQUATION ANALYSIS OF THE SOCIAL CAPITAL FACTORS INFLUENCING PHYSICAL ACTIVITY

NISHIDA, S.

TOYOOKA PUBLIC HOSPITAL

INTRODUCTION:It is well known that social capital promotes healthy behaviors. Several mechanisms have been hypothesized as to why community social capital may promote physical activity. There are numerous studies of the effects of social capital factors on physical activity. However, few studies have examined the structure of these effects. Thus, this study aimed to investigate the effect of social capital factors on physical activity among Japanese adults by using structural equation modeling.
METHODS: A randomly selected sample of 2,500 residents of Toyooka city were mailed a questionnaire. Social capital was divided into trust of others in the community, social engagement, greetings, helping each other, and interaction with their neighbors. Structural equation modeling was conducted to determine the associations between social capital factors and physical activity.
RESULTS: A total of 397 questionnaires were completed and returned. The study participants, mean age (standard deviation; SD) was 56.9 (16.9) years. Trust of others in the community was found to directly affect physical activity (.13). Greetings, helping each other, and interaction with their neighbors did not directly affect physical activity; however, they had an indirect effect on physical activity through trust of others in the community. The final model demonstrated an acceptable fit (GFI = .99, AGFI = .98, and RMSEA = .03).
CONCLUSION: The present study observed that social capital factors both directly and indirectly affected physical activity among the participants. Mutual networks in the community increase trust and physical activity.

DETERMINANTS OF SEDENTARY BEHAVIOR FROM YOUTH TO YOUNG ADULTHOOD

YANG, X., KANKAANPÄÄ, A., TIKANMÄKI, M., VÄÄRÄSMÄKI, M., KASEVA, N., KALLIO, J., JÄRVELIN, M.R., KAJANTIE, E., TAMMELIN, T.

LIKES RESEARCH CENTRE FOR PHYSICAL ACTIVITY AND HEALTH, PEDEGO UNIT, MRC OULU, OULU UNIVERSITY HOSPITAL AND UNIVERSITY OF OULU

INTRODUCTION
Evidence suggests that young people spend a considerable portion of their lives in sedentary leisure pursuits, especially using electronic devices (Salmon et al., 2011). Adolescents are insufficiently physically active, partly because so much of their free time is spent sitting in front of screens at home. However, the patterns and determinants of sedentary behavior (SB) in youth are poorly understood and therefore a single strategy to decrease excessive sitting is unlikely to be effective in all countries (van Sluijs et al., 2010). We evaluated the association between SB (screen time and total sedentary time) in adolescence and young adulthood, and identified direct and indirect associations between sociodemographic and health-related factors in adolescence and SB in young adulthood.
METHODS
The sample comprised 585 individuals (male 52%) who participated in the Northern Finland Birth Cohort 1986 study in 2001–2002 (15.5±1.6 y) and in the Preterm Birth and Early Life Programming of Adult Health and Disease (Finnish acronym, ESTER) Study in 2009–2011 (24.1±0.8 y). SB was self-reported in both adolescence and young adulthood. Direct and indirect relations were tested and evaluated using path analysis.
RESULTS
In adolescence, screen time was associated negatively with female gender, school achievement, maternal education and self-rated health, and positively with annual family income. Adult screen time was predicted directly by higher screen time and lower physical activity in adolescence, and indirectly via adolescent screen time by male gender, lower maternal education, poorer self-rated health, lower school achievement and higher annual family income. The model explained 18% of the variance in adolescent screen time and 20% of the variance in adult screen time. Adolescent total sedentary time was associated negatively with school achievement, sleep time, and self-rated health, and positively with age. Adult total sedentary time was predicted directly by higher adolescent total sedentary time, and indirectly via adolescent total sedentary time by older age, lower school achievement, shorter sleep time, and poorer self-rated health. The model accounted for the same variance (14%) in adolescent total sedentary time and adult total sedentary time.
CONCLUSIONS
Adolescent SB is a relevant predictor of adult SB over 8 years. These findings imply that several sociodemographic and health-related factors may serve as useful targets for SB prevention during adolescence and the transition to young adulthood.

CURRENT STATUS OF PREFECTURAL MEDICAL AND SCIENTIFIC SUPPORT SYSTEMS FOR FEMALE ATHLETES

SUZUKI, N.1, AONO, H.2, NOSE-OGURA, S.3, KAWAHARA, T.2

1: JAPAN INSTITUTE OF SPORTS SCIENCES, 2: JAPAN SPORT ASSOCIATION, 3: THE UNIVERSITY OF TOKYO

INTRODUCTION:Many athletes striving to reach the top levels in their sports often receive various types of support from the physical education and sports associations of the different prefectures that have joined the Japan Sport Association. Female athletes undergo menstruation and its accompanying symptoms, and often encounter the female athlete triad (amenorrhea, low energy availability, and osteoporosis) among other disadvantageous conditions; their response to such conditions and measures to provide support and improve the athletic environment are important issues. However, support for female athletes below the elite levels of the sport remains inadequate, and what measures each prefecture is taking is unclear. This study aimed to investigate the current status of support systems for female athletes in each Japanese prefecture.

METHODS: We administered a questionnaire to sports medicine/sports science committee members or administrative staff affiliated with sports associations or involved in physical education in each of Japan's 47 prefectures using an online response system.
RESULTS: Responses were collected from 44 of 47 prefectures. Regarding the presence of medical/sports science-based support for female athletes, 25 prefectures responded that implementation of such measures was "ongoing," while 15 prefectures reported that such measures were "not currently ongoing." Additionally, 10 of these 25 prefectures that responded that supportive measures were "ongoing" reported that gynecological medical examinations were also offered. Regarding the handling of gynecological medical checks, some respondents answered that "examinees are advised to seek medical attention when abnormalities are discovered during medical checks, and costs associated with such care are subsidized." Among the responses from the 15 prefectures that did not provide medical or sports scientific support, some indicated views such as "We do not have the necessary human resources or skills to make implementation of such a support system feasible."
CONCLUSION: While some prefectures subsidized medical costs related to gynecological examinations, responses from other prefectures indicated that "emphasis is not placed on such support," revealing that the current status of the support systems available to female athletes varies by prefecture. To enhance medical and sports science support programs, such as cooperating with different sports organizations and sports science specialists, increasing the number of female staff, and providing opportunities for athletes to learn more about related issues is required.

Sport Management and law

BEYOND SPORT: THE EFFECTS OF "YIQI" IN THE TAIWANESE PROFESSIONAL BASEBALL MATCH-FIXING SCANDALS

LEE, P., LIN, C., TSENG, K.

NATIONAL TAICHUNG UNIVERSITY OF EDUCATION; NATIONAL CHUNG HSING UNIVERSITY

Beyond sport: the effects of "yiqi" in the Taiwanese professional baseball match-fixing scandals
Introduction
The apparent development of sports is generally culturally diverse, yet the continuous spread of corruption in sports has evolved to become a global issue. This widespread corruption within the field of sports comes in multidimensional forms and in varying contexts worldwide; particularly, match-fixing was identified at the beginning of the twenty-first century as a new scourge in sports. In order to understand the advancement of match-fixing within the Taiwanese professional baseball system, through the notion of 'yiqi' (code of brotherhood), the above study sought to link and identify those Chinese social concepts that have been instrumental in developing professional sport.
Objectives
The study attempted to understand the function of yiqi in both transactional and non-transactional behaviors in match-fixing as a form of sports corruption. It also specified the conditions under which players are more likely to be mobilized in response to stimuli concerning a code of brotherhood.
Materials & Methods
The interviews and literature review were adopted to collect data for analysis and verification. The empirical research was conducted with in-depth interviews, including syndicates, baseball coaches, and former professional baseball players and so on. The interview data is supplemented by analyses of documentary sources such as Taiwanese court transcripts of match-fixing cases, academic articles, and media and press commentaries, etc.
Results & Discussion
The results suggested that yiqi concepts can be characterized as a form in which social relations configure "support" for various groups of actors. 1. The meaning of yiqi differs between players and coaches/mafia. In the essence of yiqi, and especially in the interactions among players, yiqi functions with tacit understanding. 2. Yiqi as a sieve and a catalyst. The presence or absence of yiqi determines how proposals are evaluated by players at the first stage, and the presence of yiqi functions like a sieve which makes it more possible for bargaining at a later stage. 3. Yiqi is accelerated by trust, and empowered by "renqing" (favor). At the later stage, when bargaining starts, trust is the decisive factor. It is trust that functions in the transformation from expressive ties to mixed ties. To maintain the friendship, players are willing to help their fellows, regardless of the cost.
Conclusions
This research concludes a paradigm shift, from western theoretical traditions to oriental cultural perspectives, to explain sports corruption [match-fixing] in a society valuing more the interdependent-self than the independent-self. Maintaining collective harmony and loyalty in sibling relationships implies a senior-oriented buddy system, which helps develop the brotherhood sentiment and the ethics of seniority among baseball players. Criminal groups bribed friends/teammates to manipulate players to become involved in professional baseball match-fixing. These results show that yiqi and the manipulation of match-fixing were present in the Taiwanese professional baseball system.

SPORT POLICY LEARNING FROM SCOTLAND: A BALANCE DEVELOPMENT BETWEEN PERFORMANCE SPORT AND THE SOCIAL BENEFITS OF SPORT

JIANG, R.

NATIONAL TAIWAN UNIVERSITY OF SPORT

Introduction
Past sport policy research, when referring to the sport studies for United Kingdom, it always put emphasis on England because of its outstanding performance in international competitions. However, the British sports policy should not only refer to the policy of England. Scottish sport policy might be a better reference for small states, nations, governments or areas as it has a comprehensive sport policy for the development of domestic sport and the promotion of sport participation. This study seeks to identify the nature of the development and delivery of the sport policy in the UK context focusing on Scotland sport policy.
Methods
In focusing on the analysis of Scottish sport policy, the study adopted a qualitative case-study approach, which is based on documentary material content analysis, and semi-structural interviews. The interviewees were selected on the basis of involvement in specific aspects of strategic contexts of sport development in Scotland. Two complementary theoretical approaches are adopted for data analysis, those of governance theory and strategic-relational approach, which allows us to identify how such outcomes of policy making/delivery were

mediated and shaped, and in particular how different sets of interests were implicated, how power was exercised, and whose interests were met in policy making process.
Results and discussion
From a meso-level perspective, this study explored the individual's strategic actions and relations. With a micro-level perspective, the result shows how such outcomes were mediated and shaped, and in particular how different sets of interests were implicated in the process of sport policy deliver in Scotland. Since Scottish sport developed in the shadow of their closest neighbours with whom there is an uneasy political relationship, sport is regarded in Scotland as an important vehicle for establishing and promoting a distinctive identity. In addition, in Scotland the political culture is sufficiently different from that of England, meaning that although winning medals is important, more attention is paid to the social benefits of sport. Scotland therefore has developed a sports policy that uses health and wellbeing as its main indicators

RESEARCH ON THE INFLUENCING FACTORS OF CHINESE PROFESSIONAL FOOTBALL MARKET ORDER BASED ON THE VIEW OF FOOTBALL FANS

HOU, H.
MINZU UNIVERSITY OF CHINA

Introduction
In the development of Chinese professional football, there are numerous interest subjects and diversified interest demands, which leads to unreasonable interest frictions among the government, associations and clubs, and leads to the disorder of Chinese professional football market. Therefore, to reflect on and explore the reasons for the disorder of Chinese professional football market, is one of the important topics that the football researchers and managers should focusing on. Based on this, the research only starts from the perspective of fans, which is the basis for the survival and development of professional football, the study deeply discusses the factors affecting the market order of Chinese professional football, and provides a reference path for reshaping and maintaining the market order of Chinese professional football and promoting the healthy development of Chinese professional football.
Methods
Through literature review and expert interviews, we designed a questionnaire . The validity and reliability of the questionnaire were 0.83 and 0.81, which met the research requirements. We conducted a questionnaire survey on 8,000 on-site fans in 26 divisions of China professional football league. A total of 6,719 questionnaires were collected and 6,131 were valid. Aldosary importance index formula and factor analysis were used to statistically process the questionnaire data.
Results
1) The factors affecting the order of Chinese professional football market (the importance index is greater than 60%) are in order of influence from high to low: local teams do poorly in domestic leagues(F1), national teams at all levels performed poorly in intercontinental and world competitions(F2),"match-fixing" , gambling and "black whistle" affect the match results(F5), players personal athletic ability is poor(F3), the industry organization has insufficient public relations capacity for negative impact(F16).
2) According to the results of factor analysis, four common factors influencing the order of Chinese professional football market: competitive ability and competition results factor, professional quality of fans and practitioners factor, management level of industrial organizations factor and professional football regulation factor.
Discussion
1) From a single factor, the most important issues affecting the order of Chinese professional football market is the poor competitive level of the team, including the poor performance of the local teams and the national teams at all levels in the intercontinental and world competitions.
2) On the whole, behind the various concrete problems affecting the order of Chinese professional football market, there are common factors such as competitive ability and performance, the quality of fans and practitioners, the management level of industrial organizations and the supervision of professional football market. These common factors constitute the main factor system influencing the order of Chinese professional football market.
3) Improving the teams group competitive ability is an important way to standardize the order of Chinese professional football market and improve the quality of Chinese professional football market.

SOCIAL BENEFIT OR POLITICAL VALUE? THE NATURE OF SPORT DEVELOPMENT IN MACAU

HUANG, J., YANG, I.
NATIONAL TAIWAN UNIVERSITY OF SPORT

Introduction
A successful sport development involves many factors, which is in needs of various kinds of support. The crucial factor is mainly so-called 'resources', specifically to say, human resources(people) and financial support(money). What if there is a place with high population, vigorous association/community/club culture and development of gambling as a main industry, how does its sport development look like? In this sense, this study aims to explore the nature of sport development in Macau with a focus on its complicate network of stakeholders.
Methods
This study adopts a qualitative approach, which is based on documentary material reviews and semi-structural interviews to generate a framework by which to analyze the sport development system in Macau. Eight interviewees were selected on the basis of involvement in specific aspects of sport development in Macau. Interview transcripts and government reports/proceedings of parliamentary debates were subject to coding employing Nvivo 11 qualitative data analysis software, and coding and analysis were undertaken employing an ethnographic content analysis approach.

Results and discussion
There are numerous sport clubs in Macau. Of all 7000 registered associations/ communities/clubs, over 30% associations/communities/clubs are sport related. In the empirical work, interviewees didnt mention the hardship and shortage of funding. Therefore, on the strong basis of financial support and human resources, the nature of sport development in Macau has essentially changed from the promotion of performance sport and sport participation to the competition of power and resources between interest groups. Furthermore, in the case of special electoral system in Macau, some of the Legislative Assembly members are elected from sport clubs. The development and interaction between sport clubs has become a channel to get into the politics. By showing the integration of politics and sports, the stakeholders could receive political interests, or even get connected with the Beijing government. The outcome of promoting sport might not be the increasing of social benefit anymore, but being a part of surplus value after pursuing the political interests.

THE STRATEGICAL PLAN FOR SPORT IN THE CITY OF LJUBLJANA– FOCUS ON ETHICAL AND SOCIAL CONSIDERATIONS?

BON, M.

UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

Aim of the research
The research problem is the current situation in sport in Ljubljana, including premature specialisation, focus on results, lack of top-level results, poor club management, and the need for a new strategical plan with an increased focus on ethical and social values.
Theoretical background or literature review
The document "Strategy for the Development of Sport in the City of Ljubljana 2008-2012" (Bon, Kolenc, Tomc, Peršolja 2018) was the first in the history of Ljubljana. The most important strategical goals were: a different organization of sport. The purpose of this study is to present a new model with ethics and social considerations as the main priorities.
Methodology, research design, and data analysis
Within the theoretical research, the main methods used were description and comparison, while whole- and part-methods were applied throughout the remainder of the study. The current situation was analysed using the deduction method. Data were collected via interviews; some of the data were also based on the personal observations of authors.
Results, discussion, and implications/conclusions
We present one theoretical model of the strategical plan: Sport in Ljubljana until 2023, with the main statements:
• Ethical values and social aspects should be the top priorities in MOL
• Children (or their parents) should not need to pay for after-school sporting activities (extra curriculum), which are made available at least twice per week
• Sport for all: MOL shall maintain and manage outdoor (free) and indoor facilities
• MOL shall organise salaries for (100) coaches in different sports disciplines
• Competition up to the age of 12 years (with some exceptions) should not be supported by MOL
• Sport festivals should be preferred over competitions
• Special monthly awards for fair-play activities (not competition and results)
• Award of the year: most ethical behaviour
• In media: (only) reports about fair-play activities (not about competition results)

Sport Statistics and Analyses

A DISCUSSION OF THE CONSTRUCTION OF CHINA'S NATIONAL PHYSIQUE MONITORING PERFORMANCE EVALUATION FEEDBACK SYSTEM

LIU, X.

CHINA INSTITUTE OF SPORT SCIENCE

Foreword
In China, evaluation of the governmental administration of public utilities is an important work, which can be more facilitated only by scientific and reasonable evaluation and timely feedback. Therefore, establishing a complete system of performance evaluation indicators is indispensable. However, in China, there is no national system of overall work performance indicators in the fields of science and technology, education, health and sports, and it is very important to develop a feasible evaluation feedback system, improve the national physique monitoring system, standardize and regulate the national physique monitoring activities in China and guide its overall and healthy development.
Methodology
The current status of China's national physique monitoring system evaluation feedback system has been combed and analyzed using literature review and other methods.
Results
Based on the 360-degree performance evaluation feedback system, this study combines the quantitative assessment of the target responsibility system and 360-degree qualitative assessment and employs a quantitative and qualitative approach, whereby the weight of

quantitative assessment of the target responsibility system accounts for 60%, that of the 360-degree quantitative assessment accounts for 30% and that of leadership appraisal accounts for 10%. The construction of China's national physique monitoring performance evaluation feedback system has been discussed in terms of the standardized indicator system, standardizing the evaluation procedure and increasing the operational applicability, establishing and improving the process for application of evaluation feedback results, improving the performance evaluation regulations and promoting the legalization of performance evaluation.
Conclusion
In light of the characteristics of the national physique monitoring system, the approach to "sustaining and developing" shall continue to be followed, the performance awareness increased, greater attention paid to performance evaluation feedback, the top-down evaluation model be combined with the bottom-up evaluation model, 360-degree performance evaluation feedback brought in order to create a multifaceted evaluation feedback system oriented towards the public demand for physical health, led by the internal governmental assessment, attended by the general public extensively and in depth and assisted by third-party evaluation organizations.

LATERAL DIFFERENCES OF THE UPPER EXTREMITY CIRCUMFERENCES AND THE HAND GRIP STRENGTH IN YOUNG HANDBALL AND TENNIS ATHLETES

BAYIOS, I., NOUTSOS, K., BAGIOS, G., ROUSANOGLOU, E.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION:Lateral differences are a great concern in sports where one upper extremity is predominantly used, particularly for athletes in a developmental age stage (1). This study aimed to examine the lateral differences of the upper extremity circumferences and of the hand grip strength in young handball and tennis athletes, as well as to compare the differences between the two sport groups.
METHODS: Twelve handball athletes (12.5±0.5 yrs, 156.8±8.2 cm, 51.6±10.9 kg) and twelve tennis athletes (12.5±0.4 yrs, 153.7±5.4 cm, 46.5±3 kg) participated in the study. The right upper extremity was the dominant one for all athletes. The circumferences of the right (R) and left (L) arm and forearm were measured in a relaxed muscle state. The mean of 3 measurements for each site was inserted for statistics. The R and L: hand grip strength (3 trials each) was measured with a dynamometer (Lafayette Instrument, Co Indiana, USA, 100 gr accuracy) while standing and with the upper extremity at the side of the body. In all trials, they were instructed to develop their greatest strength and maintain their effort for 3 sec and the peak reading was recorded. The mean of the 3 trials (3 trial mean) and the trial with the greatest peak reading (maximum trial) was inserted for statistical analysis. Statistics included paired t-test for the laterality comparison and one way anova for the sport group comparison (SPSS v.25, $P<0.05$).
RESULTS: Laterality comparison: The circumference of the arm and the forearm did not differ significantly ($P>0.05$) between the right and the left upper extremity, both in the handball as well as in the tennis athletes. The 3 trial mean and the maximum trial hand grip strength were significantly higher in the right than the left hand, both in the handball (R: 22.0±4.6 kg, L: 18.5±4.1 kg, P=0.030, and R: 23.8±4.7 kg, L: 20.1±4.7 kg, P=0.031, respectively) and the tennis athletes (R: 20.0±3.8kg, L: 16.7±2.9 kg, P=0.013 and R: 21.1±4.0 kg, L: 17.6 ± 3.0 kg, P=0.012 respectively).
Sport group comparison: The arm and the forearm circumferences were significantly greater in the handball than in the tennis athletes for both upper extremities (P=0.02 for all). No significant difference was found in the 3 trial mean ($P>0.05$) and the maximum trial ($P>0.05$) handgrip strength between the two sport groups.
CONCLUSION: Overall, the values were within the normal range for young athletes (2). The about 16% lower strength in the left than the right hand grip may be explained by the predominant use of the right upper extremity in both the handball and the tennis athletes. The greater body height and mass of the handball athletes may be associated to a developmental precedence of this sport group, which in turn may explain their significantly greater arm and forearm circumferences(1).

THE QUANTITATIVE CHARACTERISTICS OF ACTING IN THE FREE ROUTINE OF YOUTH ARTISTIC SWIMMERS

NOMURA, T.

KYOTO INSTITUTE OF TECHNOLOGY

INTRODUCTION:Although the performance analysis of the adult swimmers in Artistic Swimming has been found so far, few studies targeting youth are found. The purpose of this research was to clarify the quantitative characteristics of acting in the free routine of youth Artistic Swimmers.
METHODS: Twenty subjects youth Artistic Swimmers aged 13-15 who participated in a national level solo competition were targeted.
A digital video camera (Sony HDR-PJ 800, shutter speed at 1/2000, resolution at 1920 x 1080, 59.94 fps) was used. The camera was fixed to a tripod, and it was set on the side upper part of the stands. For the camera setting, an angle of view covering the competition area was secured. For analysis, the movie file was converted to 2.00 fps AVI file using AviUtl100.
For digitizing, Note-player2 which was 2-dimensional DLT analysis software made by the windows API and Visual Basic for Application was used. Items related to performance time, to the moving pattern (trajectory, area etc.), and to the movement speed were calculated.
RESULTS: The total performance time was 130.2 ± 5.52 s. The performance distance was 53.5 ± 6.84 m, which was equivalent to the report on the world level (Homma et al., 2002) and the report on the Canadian National level (Alentejano et al., 2008). The space of performance was 79.7 ± 29.28 m^2, narrower than the report on the world level (Homma et al., 2002). The acting area was 49.1 ± 17.67 m^2. The average speed was 0.36 ± 0.050 m/s. The moving speed at 0.15 m/s or less was 27.9 ± 8.11%, and the moving speed at 0.15 to 0.3 m/s was 24.1 ± 3.97%, occupying more than half of the whole. A relatively fast movement of 0.9 to 1.05 m/s was 3.2 ± 0.99%. This ratio was low, but a significant correlation was observed with the free routine score ($r = 0.43$, $p < 0.05$). Except for the centre point of the performance space, there was no significant relationship between the other items and the free routine score.
CONCLUSION: This study showed that the spread of space has little effect to judge on youth Artistic Swimming. In addition, the score was influenced by the performance at a fixed position, but it was suggested that a rapid movement may add dynamics to the performance.

IT'S ALL ABOUT POSITIONING – THE IMPORTANCE OF DISTANCE, ANGEL, AND INSIGHT BY THE REFEREE FOR MAKING THE CORRECT DECISION IN PENALTY SITUATIONS IN SOCCER

JOHANSEN, B.T.1, ERIKSTAD, M.K.2, NORWAY, R.G.1,3

1UNIVERSITY OF AGDER, 2NORD UNIVERSITY, 3UNIVERSITY OF STAVANGER

It's all about positioning – the importance of distance, angel, and insight by the referee for making the correct decision in penalty situations in soccer

Bjørn Tore Johansen1, Martin Kjeøen Erikstad2, & Rune Giske, Norway1,3

1University of Agder, 2Nord University, 3University of Stavanger

Introduction

Johansen and Erikstad (2018) have found that the referees had a poor starting position to assess the penalty situations where they landed on a wrong decision. Mallo et al. (2012) have demonstrated that a short but appropriate distance for referees will ensure that they gain more insight into a situation and the likelihood of making the most correct decision will increase. The aim of this study was to investigate the referees' positioning in the field where top referees in soccer make a correct decision in penalty situations.

Methods

Two expert panels, consisting of four top-class referees and four top-class players respectively, assessed 98 video clips of potential penalty situations in Norwegian premier league. The situations in which both expert panels considered that the match referee made a correct decision (N = 28) were then analyzed based on recommended technical refereeing criteria and guidelines (i.e., the referees distance to, angle to, and insight into these penalties situation; UEFA, 2018).

Results

The results indicated that the referee when making a correct decision had an appropriate distance, i.e., less than 10 meters (10 situations) and between 10-20 meters (14 situations) in 24 of the 28 penalty situations studied and in four of the situations was the distance bad, i.e., longer than 20 meters which the limit of the recommended standard set by FIFA (2018). Further, results revealed that the referee had a good angle in 22 situations and good insight into 18 situations. In only four situations did the referee had a bad angle and in only three situations was the insight bad.

Discussion

The match referee had an appropriate distance, angle, and insight to assess the penalty situations when making a correct decision. In contrast, Johansen and Erikstad (2018) found that the referee had an extended distance to the penalty situation in 12 of the 14 situations where referees landed on a wrong decision. The referees' positioning seems to increase the likelihood of making the most correct decision in these situations (Mallo et al., 2012). The psychological demands for excellent performance among soccer referees are substantially increasing (Slack et al., 2013) the referee's starting position appears vital for making a correct decision that may influence the match result (e.g., penalty situations).

DATA VISUALIZATION IN SPORT - TAKING NATIONAL MIDDLE SCHOOL ATHLETE GAMES FOR EXAMPLE

CHEN, J.

NATIONAL CHUNG CHENG UNIVERSITY

24rd annual ECSS Congress Prague/Czech Republic, July 3-6 2019

Data Visualization in Sport - Taking National Middle School Athlete Games for Example

Chen, J.Y., Yao, Y.Y., Chen, Y.Y., Lin, Z.R.*

Sport and Leisure Education, National Chung Cheng University

INTRODUCTION :

This study used the results of the 2017 National Middle School Athlete Games in The National Database of student Athlete. Using data visualization technology, it was clear in the categories of Athletics, Aquatic Sports, Martial Arts and Ball Sports that Body Mass Index (BMI), regional (county) and the performance of Taiwanese aborigines. This technology is applied to the results of sports games, with the characteristics of convenience and effective presentation of performance data.

METHODS :

This research method used Power Business Intelligence (BI) software for data visualization analysis and descriptive statistical analysis was carried out on the data including Body Mass Index, athletes representing counties and cities and Taiwanese aboriginal groups.

RESULTS :

1. There were four types of sports in the National Middle School Athlete Games. Due to the relationship between sports attributes, the BMI values of men and women in different sports types were different. The BMI is higher on Athletics and Martial Arts athletes. The composition of the index in weight classification reflected the BMI value index of the crowd.

2. Taiwanese aboriginal players accounted for a higher proportion of the number of people who won on Athletics and Martial Arts athletes which got 312 medals and 15% in total. The geographical location of Taiwan was 39% in the north, 21% in the middle, 12% in the south and 29% in the east. Most of the medals in Taoyuan County and New Taipei City were inconsistent with Hualien County (17%), Taitung County (14%), Taoyuan City (13%) and Pingtung County (11%), which were the main residences of Taiwanese aborigines. The ratio of northern Taiwanese aborigines participating in competitive sports was higher.

CONCLUSION :

This study provided a quick overview of the data by analyzing the large amount of data through data visualization, and cross-checking and digging down the data. The above showed and verified that the Taiwanese aboriginal people have better athletic talents. It was suggested that future research can be conducted various athletic ability assessments and training through scientific selection, training and coaching for the Taiwanese aboriginal sports athletes. This method was also applied in different fields, and it was believed that there would be more outstanding sports performance.

THE RELATION BETWEEN THE MONTHLY WEATHER IN 2017 AND INFANTS' MODERATE TO VIGOROUS PHYSICAL ACTIVITY IN THE MORNING.

DEMURA, T.
JIN-AI UNIVERSITY

INTRODUCTION:The degree of an individual's physical activity may be affected by variable factors such as exercise habits and lifestyle as well as non-variable factors like seasonal and climatic elements such as temperature, rain, wind, and snow, prevalent in Japan's climate. This research aims to investigate the relation between the weather of each month in 2017 and the extent of infants' morning activity.
METHODS: The subjects of the study were 21 infants (11 boys and 10 girls) attending a four-year-old class in a nursery school in Fukui Prefecture. Using an activity meter with a built-in triaxial acceleration sensor (Active Style Pro HJA-750C, Omron Healthcare, Japan), subjects' physical activity was measured from the time of arrival at the nursery school in the morning until lunchtime from January to December 2017, and the average values of physical activity time over medium strength (<4 metabolic equivalents, moderate to vigorous physical activity (MVPA) (Sasaki et al., 2013)) were used for evaluation. Weather data, which included monthly mean values of precipitation, temperature, and sunshine hours at a time point in the measurement location, was obtained from the website of the Japan Meteorological Agency. Regression analysis was carried out using weather data (rainfall amount, temperature, daylight hours) as the dependent variable and the MVPA of each month for each gender as the independent variable. The statistical significance level in this study was 5%.
RESULTS: As a result of the regression analysis, a quadratic regression equation was obtained between MVPA and temperature for both males and females (boys: $Y = -0.238 x2 - 7.680 x + 88.42$ (R2 value: 0.42), girls: $Y = -0.198 x2 - 6.584 x + 96.27$ (R2 value: 0.37); $p > 0.05$) . However, the regression equation of the weather data and MVPA was not significant.
CONCLUSION: In our previous study, a relationship was found between the number of steps and the temperature, it was clear from the results that seasonal factors such as temperature, precipitation, and sunshine hours do not have a significant influence on infants' MVPA.

PATTERNS OF SPORTING HABITS AND MOTIVATIONAL FACTORS OF DOING SPORTS AMONG THE HUNGARIAN STUDENTS

PALUSEK, E., SZEKELY, M.
EÖTVÖS LORÁND UNIVERSITY OF SCIENCES

Introduction
Eötvös Loránd University of Sciences has surveyed sporting habits of the Hungarian students. The aim of the project is getting deeper knowledge about the frequencies of physical activities and the correlations between the frequencies and the fields of disciplines chosen by the students. We also investigated the most important motivational factors associated with sports and the reasons of lack of physical activities.
Methods
In 2011 our online survey was filled in by a huge sample of students from most of the Hungarian universities. We made it representative by weighting based on the data of a representative online survey (filled in by 1 500 students) in 2013. In 2019 we will measure the sporting habits of our target group again.
Results and discussion
Results show that only quarter of the students reaches the WHO's recreational minimum which takes 150 minutes a week, but there is another 48,1 percent doing sports but not enough (only once a week). This is the critical mass which can be motivated to do more physical activity and perhaps could take in a part of the inactive students (28.9 percent). The average Hungarian student does sports 87.64 minutes a week. There is a significant difference between men and women (112.13 vs. 68.29 min/week). In the ideal case men would spend 199.5 minutes to physical activities but women's frequency (142.1 min/week) doesn't reach the recreational minimum nor in ideal case.
We found a significant correlation between the fields of disciplines and the frequencies of physical activities. The students of political and sport sciences do much more sports than the others. The most inactive students deal with pedagogy and arts. Among the women the main motivational factor is to look better, while men do sports to develop their physical abilities. On the third hand, there is a different motivational patterns of the students doing individual sports, paired (combat) sports and team sports. We found, the type of recreational sports choosed by our students are varied consequently by typical stimulus: e.g. motivation of improving fitness or looking better indicate to do single sports, developing new skills or making new acquaintances connect to twosome games, and spending time with friends or competing are characteristic team sports.

ECONOMIC ORGANIZATIONS, ESPECIALLY THE SPORT ORGANIZATIONS EFFECTS ON CORPORATE SOCIAL RESPONSIBILITY ON YOUTH AGED ATHLETHES

TÓTH, D.Z., SZEGNERNÉ, D.H., GOSI, ZS.
EÖTVÖS LORÁND TUDOMÁNYEGYETEM ELTE

INTRODUCTION:The economic organizations especially, the sport organizations have determinative role in corporate social responsibility. Due to the special place in the economic system, the sport economic sector has many effect on the young athletes Babiak and Trendafilova (2010). We are able to find numerous good examples in Major League Sports in the US, where, plenty of franchise players are heavily involved in charity work, for instance, raising funds, establishing foundations, visiting sick people and etc. The CSR (Corporate Social Respontibility) has a positive impact on the society, while it also has a stimulating effect on the economics as a side effect (Bryan at all, 2015). There are a lot of companies in Hungary who recognized the importance of this trend, however, we cannot find a lot of good examples in the sports sector yet Tóth, Gősi (2018). In this essay, we researched the sport organizations effects on corporate social responsibility on youth aged athletes.
METHODS: In the first phase of this study, we were processed and meticulously examined the data, in which CSR has changed its meaning and function, as the society requirements developed over time. Right after the data processing phase we created a survey, in which the population was 40 youth basketball players (n=40). During the first assessment, we measured the IRI (Interpersonal Reactivity Index) and the PANAS SHORT FORM, and we applied our, self created survey which was about the habits of using the internet in general.
During the second measurement phase, we repeated the whole IRI and PANAS survey, after watching short commercial videos of the NBA and Decathlon Hungary, in which we could find CSR elements.
RESULTS: The respondents claimed that they are using the NET 153,65 minutes a day in general. The initial IRI test resulted 80,9 score, which is totally fits the boundaries and considered normal for this age group. There is a significant relationship between the two indicators (Pearson Correlation 0,527), which shows that, if they use the internet more, the higher the IRI value gets. The only problem with this, it that the fact that, the highest score does not always mean the correctness of the given answer. As a result of the intervention, the rate of vocation raised (avg. 3,85->4,3) and the intrepidity rate raised as well (avg. 4,1->4,4).
CONCLUSION: Considering American and Western European instances, there is a clear view in which the Sport Organizations realised the importance of CSR Babiak, Wolfe (2006). We can talk about any action, donation, we can make out the main purpose of these activities. In Hungary we lack of this kind of a documentation of these actions, by the result of this, the respondents could not express themselves in their own words defining what CSR is. The conclusion of this, if they see more contents regarding CSR, their emotional maturity will benefit from it significantly.

Sport Technology

POSTOPERATIVE PHYSICAL ACTIVITY MONITORING BASED ON MHEALTH APPLICATION

HO, T.W., WU, J.M., TSAI, H.H.
NATIONAL TAIWAN UNIVERSITY

INTRODUCTION:The only curative therapy for Gastric cancer (GC) are complete surgical resection and endoscopic submucosal resection, both of which may cause declined physical activity (PA) and quality of life, especially in patients receiving postoperative chemotherapy or chemoradiation. PA is a well-established parameter that not only assesses the general condition, but also monitors the patients recovery. Traditional perioperative care depends on medical professionals inquiring patients' PA; however, these self-report measures are not autonomic and unreliable for analysis. To address the above issues, this study aimed to provide a scalable and flexible platform based on mobile health (mHealth) to assist the practice of medicine and public health supported by mobile devices for the monitoring of postoperative physical activity on patients with GC.
METHODS: We developed an iOS/Android app that facilitates patients to record perioperative clinical variables and transmit digital images of surgical wound to the medical staff using smart phone and smart watch. We enrolled patients undergoing gastrectomy for GC at an academic teaching hospital between January 2016 and December 2017. Demographic characteristics and clinical outcomes of study subjects include age, gender, body mass index, minimal invasive surgery, Charlson Comorbidity Index (CCI), method of gastrectomy, cancer histology, major complication, data of PA, and so on. All statistical analyses were performed using SPSS version 23 (IBM Corporation, Armonk, NY, USA). This study protocol was approved by the Institutional Review Board of the National Taiwan University Hospital (201412040RIND). This study was supported by a grant from the Ministry of Science and Technology, Taiwan (MOST 106-2628-E-002-004-MY3).
RESULTS: Of the 43 analyzed subjects, 51% were males, and the median age was 68 years. For predicting early hospital discharge, four predictors of the decision tree are improved physical activity, minimal invasive surgery, the method of gastrectomy, and cancer histology. This experimental result is the same as the predictors in the analysis of multivariate Logistic regression. The root node of decision tree for predicting early hospital discharge indicates that the percentage of early discharge on patients with and without improved PA are 88% (15/17) and 15% (4/26), respectively.
CONCLUSION: This study demonstrated a scalable and flexible platform based on mHealth to assist the practice of medicine and public health supported by mobile and wearable devices for the monitoring of postoperative physical activity on patients after major gastrectomy. To our best knowledge, there is no well-documented that developing a comprehensive app to derive the objective data of PA as a reliable clinical parameter for gastrectomy patients. Our findings are also encouraging and add further support to implementation of mHealth as part of perioperative care.

ALLOCATION OF ATTENTIONAL RESOURCES IN UNIVERSITY STUDENTS IN DUAL-TASKING SITUATIONS WITH BICYCLE SIMULATOR

SHIMODA, M.1, FUKUMOTO, H.1, IWAMI, M.2, HIGASHIURA, T.3, SAKEMOTO, N.4
1,2: TOKYO UNIVERSITY OF AGRICULTURE AND TECHNOLOGY, 3: ASIA UNIVERSITY, 4: SEIWA UNIVERSITY

INTRODUCTION:During bicycle riding, riders must appropriately allocate their attentional resources to various circumstances such as traffic signals, pedestrians, cars, and bicycles. It is well known that as riding becomes more difficult, riders' attention to others decreases. For example, when avoiding pedestrians on a narrow sidewalk, riders may be unaware of a change in the traffic signal from green to

red. In this study, we examined the effect of task difficulty on university students' attentional resource allocation in dual-tasking situations using an event-related brain potential, P300.
METHODS: Eleven university students rode a bicycle simulator at the same pace as their daily bicycle use. They were asked not to go out of the course displayed on the simulator screen. As conditions of task difficulty, three widths of the course were used, i.e., 1 time (0.55 m), 1.5 times (0.825 m), and 2 times (1.1 m) the handlebar width, respectively. During a traditional auditory oddball paradigm (320 s), participants responded to rare target tones by pushing a button while running the simulator.
RESULTS: Average speeds of bicycle simulator were not changed in the three task situations. Time of riding beyond the course width was longer in the 0.55 m task (27.3 s) than the other two tasks (3.3 s and 5.7 s), but the differences were not statistically significant ($p = 0.067$). Amplitude of P300 was smaller in dual-tasking situations than in the control (oddball-only) situation, but it was not affected by task difficulty. Latency of P300 was affected by task situations, but reaction time was not.
CONCLUSION: Course width as task difficulty did not affect university students' attentional resource allocation during bicycle riding.

RELIABILITY AND VALIDITY OF ULTRA-SHORT HEART RATE VARIABILITY (HRV) FEATURES

KURZ, E., ULLRICH, B.W., LEHMANN, C., MENDEL, T., HOFMANN, G.O., SCHENK, P.

MARTIN-LUTHER-UNIVERSITY HALLE-WITTENBERG

INTRODUCTION:Monitoring the current state of the cardiac autonomic nervous system and exercise management derived therefrom are increasingly used in athletic as well as patient populations. Available mobile applications and wearable sensors enable access to everything from long-term to ultra-short heart rate variability (HRV) features. However, the validity of ultra-short HRV features remains unclear. Thus, this preliminary study aimed at comparing ultra-short HRV features using different time intervals to short-term 5-minute HRV features that served as reference.
METHODS: Six healthy and non-pregnant women (age: 24-33 years, BMI: 19-26 kg/m²) volunteered to participate in this study. The heart rate was measured with an ECG amplifier (sampling rate 2048/s, DeMeTec, Germany) upon waking and in lying supine position for five minutes (reference), after 15 minutes rest. HRV analyses were performed with Kubios software (ver. 3.2.0) on the reference data as well as four ultra-short time intervals (30, 60, 90 and 120 s). The following six HR modulation features were used for comparison: the RMSSD and SDNN (time domain), the FFT and AR high-frequency power (frequency domain), and the standard deviation of instantaneous beat-to-beat R-R interval variability (SD1, SD2) from non-linear analyses. Differences were visually inspected using the Bland-Altman method. Possible systematic effects were explored for each interval, using Student's paired t tests and effect size (ES) statistics. Linear associations (Pearson's r), relative (ICC) and absolute reliability (standard error of measurement, SEM) measures were calculated.
RESULTS: Overall, t tests showed no systematic differences between the time intervals investigated and the five minutes' reference for each HRV outcome. However, ES statistics revealed small to moderate effects for 30, 120, and 150 s intervals, whereas only trivial ES was found for 60 and 90 s intervals. Pearson's r (0.89-0.99) as well as ICC (0.81-0.99) showed very good agreement for the selected HRV features and increased with longer intervals. Subsequently, SEM values decreased with longer intervals. The shorter intervals of the frequency domain outcomes, however, revealed the largest bias, limits of agreement and SEM.
CONCLUSION: Judging autonomic heart rate modulation is strongly dependent on the length of recording (acquisition duration) and the domain of the outcome. However, these results are limited to a small sample size. Trivial effect sizes suggest that the selected time domain and non-linear features of the 60 as well as 90 s intervals can be considered as good surrogates for short-term HRV when investigating at resting condition. Accordingly, high-frequency power estimates are not recommended when examining HRV features of ultra-short time intervals.

VISUAL BEHAVIOR OF RECEIVER IN VOLLEYBALL DIGGING

UMEZAKI, S.

TENRI UNIVERSITY

INTRODUCTION:In modern volleyball, the receiver is required to instantaneously and accurately predict and judge the toss direction and the spike course. The purpose of this study was to compare and examine the visual behavior of the receiver for different skills from the perspective in volleyball digging. We hypothesized that the timing of the activation of eye activity of advanced players is faster than that of unskilled players, and that much information can be obtained from observing setters and spikers.
METHODS: The study examined 3 advanced and 4 unskilled participants who received balls from unexpected three directions (i.e. left, middle, right) at random. Eye movements of receivers were recorded using a goggle type eye movement measurement device (Tobii glass 2, by Tobii Co.). Five of each direction of toss were carried out randomly for a total of 15. The scope of analysis of the investigation was from the receive impact to the spike impact of opponent for the 5 spikes from the left. The receiver's performance was evaluated in a 3 stages.
RESULTS: Advanced players had higher performance scores than unskilled participants. Also, the means percentage of the viewing duration of the advanced participants on the received ball and tossed ball was higher than the unskilled participants. On the other hand, unskilled participants had a high proportion of directing their eye movement to the space between the ball and the player, or from player to player. In timing of start to view setter and spiker, there were no differences observed for the two groups
CONCLUSION: This study revealed that advanced players had a higher rate of eye fixation on the ball. It is thought that by drawing a slightly different parabola for each play, they accurately determine the balls trajectory, its properties etc., which is then used to appropriately predict and judge the movement of the next player to touch the ball. Also, compared to advanced participants whose rate of pursuit the ball was high, unskilled participants had a high rate of eye fixation on the space, while advanced players used foveal vision, unskilled players used peripheral vision which suggested a higher potential to get the ball.

ACCURACY OF THE OPTICAL HEART RATE MONITOR POLAR OH1 AT REST AND DURING EXERCISE

GILGEN-AMMANN, R., SCHWEIZER, T., WYSS, T.

SWISS FEDERAL INSTITUTE OF SPORT MAGGLINGEN

INTRODUCTION:Several options of optical heart rate (HR) measurement devices have been introduced to the market. Previously, it was shown that best feasibility during use was demonstrated when worn on the upper arm in comparison to traditional chest- or wrist-worn devices (Beeler et al, 2018). The aim of the present study was to assess the accuracy of the Polar OH1 optical HR monitor worn on the upper arm at rest and during different exercise modes and intensities.
METHODS: Twenty volunteers (12 male; 30.1 ±5.7 years; 1.7 ±0.1cm; 69.5 ±8.3kg; VO2max of 53.9 ±7.4ml/min*kg) performed seven activities from sitting to floorball in a semi structured indoor environment for 10 minutes each with 2-minute breaks in between. The Polar OH1 (1Hz; Polar Electro Oy, Kempele, Finland) was fitted to the non-dominant upper arm and was compared against the criterion measure Polar H10 chest strap (1,000Hz; Gilgen-Ammann et al., under review).
RESULTS: The Polar H10 and the Polar OH1 reported overall mean ±SD HR values of 111.0 ±34.5bpm and 110.9 ±34.4bpm, respectively, with a strong correlation of r = .999 ($p < .001$). The mean absolute percentage error (MAPE) was 0.4%, ranging from 0.1% - 0.9%. The systematic biases ±limits of agreement of the Polar OH1 were -0.4 ±0.7bpm in sitting and reading, 0.7 ±1.5bpm in household chores, 0.0 ±1.0bpm in free walking, -0.1 ±0.5bpm in free jogging, -0.1 ±1.8bpm in a strength training circuit, -0.2bpm ±0.8bpm in cycling on an ergometer and -0.2 ±1.1 in a floorball course. On average in all activities, 94.5% of the mean HR values over 10-second intervals were within ±5% accuracy compared to the Polar H10. The household chores revealed the lowest (85.7%) and the free and self-paced jogging the highest (99.0%) ±5% accuracy.
CONCLUSION: Compared to the MAPEs of 1% - 9% demonstrated in wrist- and forearm-worn optical HR devices (Stahl et al., 2016; Shcherbina et al., 2017; Wallen et al., 2016), the Polar OH1 (0.4%) was more accurate. Especially, in activities with arm movements the Polar OH1 outperforms other optical HR devices. In conclusion, the Polar OH1 with its placement on the upper arm provides the best wearing comfort and is recommended for precise optical HR measurements at rest and during different exercise modes.

COMPETITION EXTERNAL LOAD QUANTIFICATION IN ELITE HANDBALL PLAYERS THROUGHOUT AN ENTIRE SEASON: DIFFERENCES BETWEEN PLAYING POSITIONS

FONT, R.1,2, TREMPS, V.1, MESAS, J.A.1, CARMONA, G.1, IRURTIA, A.2, KARCHER, C.3, RECHE, X.1

FC BARCELONA

INTRODUCTION:The aim of this study was to quantify the external load of the different playing positions of an elite handball team in official matches. In this study we used Electromechanical Performance Tracking Systems (EPTS) technology. The intermittent effort nature of handball combining high and low intensity actions during competition, rises the need of using external load monitoring devises that allows for high sampling frequency recording (i.e., EPTS technology)(Barbero et al, 2014).
The EPTS Technology allow to track the movement of the player permanently in terms of external load (Distance (DIS), High Speed Running (HSR, 18 Km/h), Acceleration (ACC), Deceleration (DEC), High Intensity Acceleration (HIA) and Player Load (PL)).
METHODS: The data was gathered during 14 official games from an elite team of the top Spanish handball league (liga Asobal). The players were equipped with a recording and tracking system (WIMU PRO®, RealTrack Systems S.L., Almería, España), using ultra-wide band (UWB) technology.
A non-parametric approach (Kruskal-Wallis) was chosen after the Kolmogorov test confirm the non-normal distribution of the data. The Wilcoxon signed-rank tests with a Holm adjust was used to test differences between playing positions.
RESULTS: The results shown significant differences between positions in DIS ($\chi 2(3, n=202)=22.456$, $p<.0001$), HSR (χ 2(3, n=202)=72.702, p<0001), HSR_min (χ 2(3, n=202)=89.18 $p<.0001$) and average speed (χ 2(3, n=202)=56.86, $p<.0001$). However, we don't find significant difference in absolute and relative (min) Player Load (χ 2(3, n=202)=8.8006, p=.319; χ 2(3, n=202)=2.8273, p=.419). Statistical analysis revealed differences in the absolute values of HIA (χ 2(3, n=202)=8.3707, p=.039) and high intensity decelerations (χ 2(3, n=202)=9.3584, p=.025), but not in relative accelerations and deceleration per minute (χ 2(3, n=202)=2.9548, p=.399; χ 2 (3, n=202)=5.2662, p=.153) respectively($p< 0,0001$), between center and line players ($p< 0.001$), and between backs and line players ($p< 0.01$). At the same time, the wing in comparison to backs ($p< 0.001$) and line players ($p< 0.001$), had more meters in absolute HSR in relation with the distance and the center run more meter of HSR_ABS_DIST than the wings ($p< 0.001$). Regarding the maximum speed, the wings and the backs had significant differences ($p< 0.001$).
CONCLUSION: The quantification of competitive external load in elite handball players showed that there were significant differences between Center vs Wings and Backs vs Line Players. However, we found similar results between Wings vs Line Players, Wings vs Backs and Center vs Line Player. Present results should help in understanding the competitive handball physical demands by playing positions.

ACCURACY OF SMARTPHONE APPLICATION COMPARED WITH PHOTOCELLS IN MEASURING CHANGE OF DIRECTION PERFORMANCE TIME

TE, T.J.1, LIM, J.H.1, CHAN, L.1, HO, T.1, LIN, R.1, HO, S.H.1, NASSIS, G.P.2

1. SPORTSLINE ASIA 2. DEPARTMENT OF SPORTS SCIENCES, CITY UNITY COLLEGE, ATHENS, GREECE

INTRODUCTION:Change of direction (COD) ability is an essential element for performance in sports (1). Existing timing systems are relatively expensive, with complicated procedure to set up. An accurate, portable measurement of COD by using a smartphone application could help sports medicine & performance team in assessing their athlete conveniently . The aim of this study was to test the accuracy of a smartphone application compared with timing gate in recording the sprint time of Pro-Agility Test (5-10-5).

METHODS: 41 lacrosse players (22 male,19 female with mean±SD age: 18.1 ± 2.2 years; height: 1.66 ± 0.08 m; body mass: 63.5 ± 13.6 kg) performed the pro agility test as their fitness test in draft for national team. The smart phone application (Professional Sports Timer; SprintTimer, Sweden) was compared with the photocells system (Speedlight Timing System; Swift, Australia) in measuring the total sprint time. The smartphone application was installed in a pair of smartphone. One of them was the start sender to initiate the starting time, the other one record the finishing time by taking slow-motion video. Participants had to put their middle finger on the screen of the start sender as the standby position. Time started counting when participants released their finger from the screen of the start sender. The finishing time was recorded when the participant's shoulder passed through the finishing line. The photocells and application were located on the same starting and finishing line. Two practice trials were given for familiarization. A total of 55 sprints were recorded and analyzed. Accuracy was assessed with correlation, t-test and the Bland-Altman plot.
RESULTS: The time recorded by the application was consistently slower than the photocells with a mean difference of 0.22 ± 0.08 s (p=.046). The Band-Altman plot showed 53 out of 55 of the data points felt into the 1.96 SD lines (-0.075 and -0.37). The mean sprint time recorded by photocells and application were 5.29 ± 0.44 s and 5.52 ± 0.46 s, respectively.
CONCLUSION: The results of this study suggest that the smart phone application might not be an accurate tool for measuring the sprinting time during a change of direction test. These findings should be evaluated taking into consideration the set up of this study.

EFFECT OF A NEW PROTOTYPE OF THERMOFORMABLE PREFABRICATED INSOLE ON IMPACT ACCELERATION IN RUNNING

JIMENEZ-PEREZ, I.1,2, REQUENA-BUENO, L.1, GIL-CALVO, M.1, APARICIO, I.1,3, LLOPIS, J.3, PRIEGO QUESADA, J.I.1,2, CIBRIÁN ORTIZ DE ANDA, R.M.2, PÉREZ-SORIANO, P.1

1> RESEARCH GROUP IN SPORTS BIOMECHANICS , UNIVERSITY OF VALENCIA. 2> RESEARCH GROUP IN MEDICAL PHYSICS , UNIVERSITY OF VALENCIA. 3> AITEX .

INTRODUCTION:The use of insoles is one of the most employed strategies when looking for impact reduction occurred during running (1). However, results are heterogeneous due to the different materials and the thickness of the layers of the insoles studied (2). A new prototype of prefabricated insole with thermoformable materials is being marketed, allowing its adaptation to the foot shape by heating it in a microwave. Thus, the aim of the study was to analyse the effect of a thermoformable prefabricated insole on impact acceleration before and after 30 min of running.
METHODS: 30 healthy runners performed 3 tests on different days. The first test was a maximum incremental test to individualize the speed of the following tests. These tests consisted of 6 progressive min warm up, and 30 min of running on a treadmill at 70-75% of their VO2max, each one with a different prefabricated insole condition, previously randomized: generic prefabricated insole as a control insole (CI) vs thermoformable insole (TI). Before each test, runners trained for two weeks with the insole condition assigned as adaptation period. Acceleration parameters (head and tibial peak acceleration, acceleration rate and shock attenuation) were measured at the beginning and at the end of the test, using two tri-axial accelerometers (BlauTic®, Spain, sampling frequency: 415 hz) placed in the non-dominant tibia and in the forehead. Data were filtered and analysed using Matlab (The Math Works Inc., USA).
RESULTS: Thermoformable insoles showed greater tibial peak acceleration [TI vs CI: 6.51(1.82) vs. 6.01(1.71)G, P=0.009] and shock attenuation [TI vs CI: 61.41(16.77) vs 56.32(16.34)%, P=0.014] only at the beginning. Tibial acceleration rate was greater with thermoformable insoles compared with control condition both at the beginning [TI vs CI: 469.93(222.47) vs (374.19(198.45)G, P=0.001], and at the end of the test [TI vs CI: 534.40(236.88) vs 448.51(220.98)G, P=0.035]. No differences in head parameters were found between insoles (P>0.05). Neither differences were found between both moments in any of the two insole conditions (P>0.05).
CONCLUSION: The thermoformable insole seems to need more adaptation time to behave as a standard prefabricated insole, due to its greater tibial peak acceleration and shock attenuation at the beginning. Moreover, the tibial acceleration rate was greater too. Thus, according to these results, this insole does not seem to reduce impacts, so it has been proposed some improvements in the product and it's necessary to continue researching in this field.

YAW AND BOAT SIDE ASYMMETRY DEPENDENT ON WIND DIRECTION IN SCULLING

SCHAFFERT, N., MATTES, K., WOLFF, S., REISCHMANN, R.

UNIVERSITY OF HAMBURG

INTRODUCTION:Sculling, a symmetrical movement, requires an asymmetric force production at crosswinds (CW) to avoid yaw (course deviation) (Sinclair et al., 2009). If scull boats yaw to one boat side (BS) because of CW, higher oar-forces have to be applied on this BS for course correction. Also, the overlap of the handle(s) (inboard lever) assumedly is an additional source for BS asymmetry in sculling (Sinclair et al., 2009). Aim was to investigate yaw and BS asymmetry of rowing technique parame-ters dependent on CW in single sculls at two wind conditions. It was hypothesized that lateral blow-ing headwind from portside yields to higher yaw compared to CW from starboard and requires an increased asymmetry in oar-force for course correction.
METHODS: Field testing was over 500-m-distances with a lateral tailwind from starboard (W1) and headwind from portside (W2) at comparable wind speed. Maximum handgrip-strength, rowing angle, oar-handle, stretcher forces and yaw amplitude were measured with 12 scullers using a mobile meas-uring system. A symmetry index (SI) between BS was calculated and compared with repeated-measures ANOVA for W1 and W2. A total of 22 variables were tested. Bonferroni-Holm-correction was used for p-value adjustment (limit at p<0.0023).
RESULTS: The 500-m-distances were done at comparable stroke rates but with a longer driving time for W2 (4.6 +/- 3.9 s). Higher yaw amplitudes were found for W2 compared to W1 that corresponded to higher SI of oar-handle force and oar-handle velocity with higher

values on starboard (ca. 40 N). In contrast, the sum of oar-handle forces showed no differences between BS in comparison of W1 and W2. Maximum handgrip-strength showed no left-right-asymmetry and can be neglected.
CONCLUSION: The results show that headwind from portside (W2) yielded to higher yaw amplitudes and higher BS asymmetry of oar-force than tailwind from starboard (W1) at comparable wind speed. This can be explained in part by the typical hand movement (right hand in front and below the left hand) but more because of the different effect of head vs. tailwind. The results agree with those for BS asymmetry from Kleshnev (2011). Further studies are necessary to compare the effects from lat-eral head and tailwind with calm. However, the control of yaw in sculling, as a requirement of row-ing technique, can affect the performance outcome distinctly.

THE ACCURACY OF APPLICATION OF WEARABLE DEVICE TO DETERMINE GAIT SYMMETRY

HO, C.S., HUANG, M.H., CHANG, C.H., CHANG, C.Y., LIN, K.C., HO, C.S.

NATIONAL TAIWAN SPORT UNIVERSITY

INTRODUCTION:Gait asymmetry as a quantitative method for sports injury prevention and prognosis assessment has significant influence in current research. Long-term asymmetry of the lower limbs may increase the chance of injury during exercise. Wearable Inertia sensors can be used to track the linear accelerations and angular velocities of the segment that have previously been confined to researchers. The combined packaging of accelerometers and gyroscopes in an inertia measurement unit have been used to analyze various parameters of human movements such as step count, cadence and segment kinematics. The purpose of this study is to determine the accuracy of lower limb symmetry calculations at different speeds using wearable devices.
METHODS: Twelve healthy men were recruited. Those who had lower limb injuries or disorders were excluded. The subjects were required to complete treadmill walking tests at speeds of 3.2 kmh-1 and 6.4 kmh-1. The motion capture system with ten high-speed infrared cameras (Vicon MX-T40-S+, Oxford Metrics, UK) and the inertial measurement units (IMU) (Trigno Wireless Biofeedback System, Delysis Inc, USA) were used in the study. The Visual3D (C-Motion, Rockville, MD, USA) software was used to calculate the kinematic and kinetic parameters. The recorded data were processed using the developed Matlab program (R2017b, The MathWorks, MA, USA). In this study, both of the peak acceleration of the two-legged tibial plateau and the vertical ground reaction force measured by the force plate were used to synchronize the Delsys inertial measurement units and Vicon kinematic parameters. SPSS 20.0 software was used for statistical analysis. Pearsons correlation coefficient was applied to evaluate the relationships between walking/running speeds and gait symmetry data measured by the motion capture system and Delysis inertial measurement units. The significant level was set at $\alpha = .05$.
RESULTS: A significant correlation between step frequency at low speed measured by inertial measurement units and motion capture system; and a significant correlation between step frequency at high speed measured by inertial measurement units and motion capture system.
CONCLUSION: The inertial sensor attached to the calf torso can accurately determine the stride frequency, which is highly correlated with the data of the motion capture system. To quantify the difference between the injured and non-injured limbs, advanced processing of asymmetry parameters should be examined in future studies.

VALIDITY OF A LOW-COST FRICTION ENCODER FOR MEASURING FORCE IN FLYWHEEL EXERCISE DEVICES

ILLERA-DOMÍNGUEZ, V.1, FERNÁNDEZ-VALDÉS, B.1, GISBERT-OROZCO, J.F.1, NUELL, S.1, GONZÁLEZ, J.1, CARMONA, G.2, MORAS, G.1, PADULLÉS, J.M.1, PADULLÉS, X.1, DE BLAS, X.3, CADEFAU, J.A.1

1- INEFC BARCELONA-UB. 2- F.C. BARCELONA. 3- BLANQUERNA-URL.

INTRODUCTION:The purpose of this study was to investigate the validity of a low-cost, easy and versatile friction encoder against a criterion measure (strain gauge) for assessing repetition mean force (Frep) in flywheel exercise devices.
METHODS: Ten young and physically active volunteers performed one set of 14 maximal squats on an inertial device (YoYo Technology AB, Stockholm, Sweden), using a moment of inertia of 0.025 kg·m2. Frep was assessed simultaneously via friction encoder (Chronojump, Barcelona, Spain), and strain gauge (Muscle Lab 6000, Ergotest Technology AS, Porsgrunn, Norway). The agreement between the criterion measure (strain gauge) and the practical measure (friction encoder) was assessed using an excel spreadsheet (1) designed to calculate the mean bias, typical error of the estimate (TEE) and Pearson correlation coefficient, all with 90% confidence intervals (CI). The standardised mean bias was rated as rated as trivial (<0.19), small (0.2-0.59), medium (0.6-1.19) or large (1.2-1.99). The standardised typical error was rated as trivial (<0.1), small (0.1-0.29), moderate (0.3-0.59) or large (>0.59). The magnitude of correlation was rated as trivial (<0.1), small (0.1-0.29), moderate (0.3-0.49), large (0.5-0.69), very large (0.7-0.89) or nearly perfect (0.9-0.99).
RESULTS: When compared to criterion measures, mean bias for the practical measures was small (0.50, CI: 0.46 to 0.54). The typical error of the estimate (TEE) was small (0.27, CI: 0.24 to 0.32). Correlation with criterion measures were nearly perfect (0.96, CI: 0.95 to 0.97).
CONCLUSION: Based on these findings the friction encoder provides a valid measure of force in flywheel exercise devices. However, as error did exist between measures, the same testing protocol should be used when assessing changes in this parameter over time, or when aiming to perform inter-subject comparisons. These findings could have valuable practical applications for strength and conditioning coaches who wish to measure force in flywheel exercises.

EVALUATION OF THERMAL RESISTANCE OF CROSS-COUNTRY SKI SHOES

MEKJAVIC, I., MEKJAVIC, V.

JOZEF STEFAN INSTITUTE

INTRODUCTION:According to International (FIS) Cross Country Ski Rules and Regulations factors that need to be considered regarding cold weather safety include the ambient temperature, duration of exposure, and clothing. For temperatures between -15°C and -25°C it is the responsibility of the competitors to obtain and follow recommendations regarding thermal protection. However, there is no indication of the minimum required thermal insulation of the clothing apparel under such extreme environmental conditions. The aim of the present study was to establish a method for evaluating the thermal insulation of cross country ski boots.

METHODS: The thermal resistance (Rt, K.m2/W) of Alpina d.o.o. (Žiri, Slovenia) cross-country ski shoes was evaluated using the Jozef Stefan Institute sweating thermal manikin. The manikin comprises 13 segments made of a silver-copper alloy. The test shoe was donned on the foot manikin, and the manikin placed in a cold chamber maintained at 15°C. During the cold exposure, the temperature of the manikin segments was maintained at 35°C. For the difference in temperature between manikin surface and amient air, and for any given segment, the insulation is a function of the electrical power delivered to the segment heaters to maintain their temperature at 35°C.
RESULTS: The thermal insulation of the Alpina cross country shoe at the position of the instep was 0.235 K.m2/W.
CONCLUSION: We conclude that it is possible to evaluate the thermal insulation of cross-country ski shoes, and that such information could be used as a recommendation to cross-country skiers regarding the minimum required thermal resistance during exposure to extreme cold conditions necessary to prevent cold injury.

RELATIONSHIP BETWEEN SKIN-GAS ACETONE CONCENTRATION COLLECTED FROM SURFACE OF EXERCISED MUSCLES AND HAND AS A NON-EXERCISED REGION FOLLOWING REPEATED KNEE-EXTENSION EXERCISE.

ITOH, H., TAJIRI, N., KATO, H., UTSU, U., MINAGAWA, A., KATO, A., TSUDA, T.
GRADUATE SCHOOL OF ENGINEERING, NAGOYA INSTITUTE OF TECHNOLOGY

INTRODUCTION:It is known that plasma acetone which is generated from decarboxylation of acetoacetate increased during submaximal running exercise (1). Yamai et al. (2) also have demonstrated increased acetone concentration in expired air and skin-gas following a submaximal cycle exercise. On the other hand, no one has demonstrated changes in skin-gas acetone concentrations directly collected from surface of active muscles following short-term repeated exercise. Furthermore, there is no data whether skin-gas concentration of exercised muscle surface would relate inactive other region or not. Therefore, the present study aimed to examine relationship in skin-gas acetone concentration between surface of exercised muscles and hand as a non-exercised region following repeated knee-extension exercise.
METHODS: Twelve healthy male students (20.5 ± 0.8 years; mean ± SD) performed 3 sets of 2-min repeated knee-extension exercise (10%1RM, time/2s) with 3-min rest during each exercise bout. The skin-gas samples were collected from quadriceps muscles (Q) and hand (H) by covering with a polyethylene bag in which pure nitrogen gas (150mL) was introduced for 30 sec, and collected in a sampling bag at rest, 5, 10, 15 min during exercise bout, and 5, 10, 20 min recovery of the exercise. Acetone concentration was analyzed by gas chromatography.
RESULTS: Skin-gas acetone concentrations significantly increased during the exercise compared to the resting values both in Q ($p<0.01$) and in H ($p<0.001$). Significantly higher resting skin-gas concentrations are observed in H compared to Q, however, higher increasing rates were found in Q (1.5 times, $p<0.01$) than in H (1.1 times, $p<0.01$) compared to the resting values. A significant relationship was found in skin-gas acetone concentration between Q and H ($r=0.462$, $p<0.001$).
CONCLUSION: Increased skin-gas acetone concentrations both in exercised leg and in hand have suggested that repeated knee-extension exercise in this study induced the production of ketone bodies in the liver, from the oxidation of fatty acids (3), and some of increased ketone bodies eliminated as skin-gas acetone from the whole body. Although higher skin-gas acetone increasing rates were observed in exercised leg compared to resting levels than in hand, there was a possibility to estimate skin-gas acetone concentration in exercised surface from concentration in hand.

EVALUATION OF THERMAL AND EVAPORATIVE RESISTANCES OF SKI GLOVES

MEKJAVIC, M., MEKJAVIC, I.B.
UNIVERSITY OF EDINBURGH

INTRODUCTION:The aim the present study was to establish a method for determining the thermal and evaporative resistances of ski gloves. Ski competitions are cancelled and/or delayed when ambient temperature falls below -25°C. For temperatures between -15°C and -25°C skiers must consider safety precautions to avoid the risk of cold injury. Providing information regarding the thermal and evaporative resistances of clothing ensembles and their components would assist skiers in determining the optimal clothing ensembles for extreme weather conditions.
METHODS: We used the Jozef Stefan sweating thermal hand manikin to compare the thermal and evaporative resistances of Outdoor Research and Blizzard ski gloves. The hand manikin comprises 16 segments made of a silver-copper alloy. Segmental thermal resistance of a glove is determined by placing the gloved thermal hand manikin in a climatic chamber maintained at 15°C, while maintaining the temperature of each segment at 35°C. Thermal resistance is determined by measuring the electrical power delivered to the heaters required to maintain the segment temperature at 35°C.
The ability of sweat to evaporate through a glove is determined by delivering water to the surface of the hand manikin with precision peristaltic pumps. The temperature of the gloved thermal hand manikin is maintained at 35°C, which is the same temperature as the ambient air. Thus any electrical power required by the heaters to maintain temperature at 35°C, must be to to the cooling power of the sweat evaporating at the manikin surface.
RESULTS: The Outdoor Research glove had an overall thermal resistance of 0.29 ± 0.004 K.m2/W compared to 0.235±0.109 K.m2/W for the Blizzard glove. The Blizzard glove enabled an evaporative rate of 13.2±0.5 g/hr whereas the Outdoor Research glove an evaporative rate of 17.0±1.5 g/hr.
CONCLUSION: Establishing a method for evaluating the thermal and evaporative resistances of gloves allows skiers to determine suitable gloves during extreme weather conditions

POLYSOMNOGRAPHY FINDINGS AND SLEEP COMPLAINTS OF ELITE ATHLETES DURING PREPARATION FOR THE RIO 2016

SILVA, A.1, TUFIK, S.2, NARCISO, F.1, ROSA, J.P.1, RODRIGUES, D.F.1, VIANA, F.1, BICHARA, J.J.3, PEREIRA, S.3, SILVA, S.3, MELLO, M.T.1

1: UNIVERSIDADE FEDERAL DE MINAS GERAIS ; 2: UNIVERSIDADE FEDERAL DE SÃO PAULO ; 3: COMITÊ OLÍMPICO DO BRASIL

INTRODUCTION:Sleep quality is an important factor which deserves to be taken into account in evaluations of high-performance athletes (Silva et al., 2012). Thus, the objective of this study was to investigate the sleep complaints, patterns and disorders of elite athletes during preparation for the Rio 2016 Olympic Games.
METHODS: The study included 146 athletes from the Brazilian Olympic Team (male: n = 86; 59%; female: n = 60; 41%) with a mean age of 24.3 ± 4.6 years. The athletes underwent a single polysomnography (PSG) evaluation at the Sleep Institute, São Paulo, during a week in which the athletes were undergoing clinical evaluations. Sleep specialists evaluated the athletes and asked about their sleep complaints during a clinical consultation. In this evaluation week, the athletes did not take part in any training or competitions.
RESULTS: 53% of the athletes reported a sleep problem during the medical consultation, the most prevalent being insufficient sleep/waking up tired (32%), followed by snoring (21%) and insomnia (19.2%). The sleep efficiency and sleep stages revealed that men had a lower percentage of sleep efficiency and slow wave sleep than the women (p=0.001 and p=0.05, respectively). The PSG examination and clinical evaluation, we found insomnia to be the most prevalent sleep disorder among the athletes (19%), followed by bruxism (7%) and sleep apnea (7%) (apnea/hypopnea index [AHI] > 5 events/hour).
CONCLUSION: The fact that we found sleep complaints in 53% of the athletes is in line with the findings in the literature, which show a similar percentage of sleep complaints such as snoring, insomnia, insufficient sleep and bruxism in the general population.

PURE ECCENTRIC EXERCISE FOR COPING WITH CANCER

YEUNG, Y.C.

COPING WITH CANCER IN LEICESTERSHIRE AND RUTLAND

INTRODUCTION:This is a preclinical trial evaluation of pure eccentric exercise for coping with cancer. The concern is whether any suggested eccentric exercise is pure eccentric exercise in the sense of minimizing the input of concentric muscle contraction. It is important to differentiate muscles being passively lengthened, actively lengthened, lengthened with assistance, and lengthened with resistance. Muscles lengthen and contract concentrically at the same time will affect the levels of oxidative stress differently to pure eccentric exercise. The aim of this research is to establish standards to ensure the input variables are pure eccentric actions, and standards of subjects for clinical trials.
METHODS: The method of evaluation is multiple case studies with multiple data collection methods. There were 14 individuals with different experiences and exposures to Qigong, Tai Chi, Standing Meditation, Internal Martial Arts, Performance art, and Eccentric Exercise. Their levels of awareness, strength, flexibility, and skill acquisition are very different. Each subject performed a series of static and dynamic activities for evaluation; which included passive stretching, active stretching, and combined stretching. The methods of data collection included visual multi-joints kinetic chain analysis to validated eccentric movement, palpation to ascertain the activation of elastic components, feedback from individual subjects, semi structured interview, and peer review.
RESULTS: The pure eccentric exercise variables are rotational stretching actions that can lengthen muscles actively or passively along the kinetic chain; the comparative advantage of rotational stretching is the capability of maximizing eccentric strength without resort to concentric muscle contraction. The subjects for clinical trial must be assessed for their range of motion, and abilities in relaxing and kinaesthetic learning. And their medications should be reviewed by experts that will not affect their levels of oxidative stress.
CONCLUSION: Performance enhancement and pedagogical concern were not included in this evaluation, as these are very much depended on the condition and abilities of individual subjects; and the design of the exercise program and method of delivery. Due to the complicity of pure eccentric exercise, it is recommended that teaching should be carried out on one to one or small group basis, and movements should be from low to moderate intensity. There is no suitable equipment for pure eccentric resistance exercise and lack of clear testing method at this stage, thus further investigation is needed.

VITAMIN D STATUS AND RELATIONSHIP WITH ROTATION CUFF MUSCLE STRENGTH IN PROFESSIONAL VOLLEYBALL ATHLETES FROM THE KOREA

KIM, D.

SUNGKYUNKWAN UNIVERSITY SCHOOL OF MEDICINE, SAMSUNG MEDICAL CENTER

INTRODUCTION:Vitamin D plays an important role in several systems of the human body. Several studies have suggested that vitamin D deficiency has significant effect on muscle weakness, insufficiency fractures, muscle recovery and function, and exercise performance. However, there is still a lack of study on the relationship between vitamin D and muscle strength as well as the vitamin D status of professional athletes. The primary aim of this study is to examine the association between serum vitamin D concentration and concentric strength profile of external and internal rotator muscles in healthy male professional volleyball players. The secondary aim was to determine the correlation between vitamin D deficiency and indices of status.
METHODS: Fifty-three male professional volleyball players (23.2±4.5 years) based in Samsung volleyball team were evaluated as part of their routine annual medical assessment. All subjects were medically cleared for participation by an orthopedic specialist. Player parameters evaluated were height, weight, blood test and shoulder muscle strength evaluation were performed. The best measure of vitamin D status is the total concentration of serum 25-hydroxyvitamin D(25(OH)D). 25(OH)D concentrations were defined using the most commonly

accepted definitions (25(OH)D < 20 ng•ml-1: deficiency, 20–30 ng•ml-1: insufficiency, above 30 ng•ml-1: sufficiency). We examine the strength of internal and external of shoulders joint by CSMI isokinetic dynamometer peak torque. Concentric shoulder external/internal peak torque was measured at 60°/s. Association between 25(OH)D concentrations and shoulder isokinetic peak torque was assessed.
RESULTS: There were 15 players (28.3%) who were deficient, 24 players (45.2%) who were insufficient, and 14 players (26.4%) who were sufficient. A total of 38 players (73.5%) were either vitamin D deficient or insufficient. However, there was no significant bivariate correlation was detected between 25(OH)D concentration and isokinetic strength of internal and external of shoulders(r =0.38, p=0.21 and r=0.29, p =0.44 respectively).
CONCLUSION: There is a high prevalence of vitamin D deficiency or insufficiency among participants in healthy male professional volleyball player. And we found vitamin D concentration was not associated with shoulder strength. However, due to the impact of vitamin D on many aspects of health, it is important for athletes to remedy deficiency. Since deficiency appears common in athletes, especially those competing indoors, athletes should consider means of increasing vitamin D status.

MUSCLE CONDITION CHANGES DURING A TRAINING CAMP FOR JUNIOR ELITE DIVERS

INAMI, T.1, NARITA, T.2, YOSHIMURA, A.3, YONEZU, T.3, YAMAZAKI, E.4, ORIKASA, Y.5, TEZUKA, T.5, SUGIYAMA, H.5, OHTANI, M.6, HIROSE, N.3, MURAYAMA, M.1

1 KEIO UNIV. , 2 HEALTH SCIENCE UNIV. , 3 WASEDA UNIV. , 4 MUKOUGAOKA PED SPORTS CLINIC , 5 SASAMOTO ORTHOPAEDIC SURGERY , 6 WAKAYAMA MEDICAL UNIV.

INTRODUCTION:It has been noted that over a 3-year period, an elite 13-year-old diver's strength, height, and weight increased, but flexibility (e.g., of the posterior muscle groups of the lower limb [PML], such as the hamstrings and triceps surae muscle) did not [1]. Flexibility decreases when muscle condition (stiffness) temporarily increases because of overuse, such as during intensive training, which leads to a high likelihood of occurrence of disorders (e.g., low back pain) [2]. Moreover, during training camps, jumping into a pool is repeated; thus, muscle stiffness in the anterior muscle groups of the lower limb (AML) (e.g., rectus femoris [RF], vastus lateralis [VL] and tibialis anterior [TA]) may also increase. To verify this hypothesis, we examined the changes in muscle condition during a training camp for junior elite divers.
METHODS: Eleven male and female elite divers from Japan's national junior team (13–17 years old) participated. Shear wave elastography was used to measure muscle stiffness, which is indicative of muscle flexibility, of the RF, VL, semitendinosus (SM), TA, and gastrocnemius medial head (GM). Measurements were taken before the training camp (PRE), and on training camp days 1 (D1) and 2 (D2). A linear array transducer was placed perpendicular to the RF, VL, and SM muscle bellies (mid-thigh). Similarly, the transducer was placed on the TA and GM, within the proximal 30% of leg length. In addition, the intramuscular difference was also measured at PRE. Two-way (time × muscle) repeated measures ANOVA, and subsequent multiple comparisons (Bonferroni post-hoc tests) were used to compare PRE, D1, and D2 measurements for each individual's muscles.
RESULTS: The Young's modulus (kPa) of each muscle in the PML (SM, GM) increased significantly from PRE to D2 ($P < 0.05$). Similarly, the Young's modulus of the AML muscles (RF, VL, TA) also increased significantly from PRE to D2. An inter-muscle difference (normalised to PRE) was detected between the RF and SM at D2. There were no intra-muscular differences in SM.
CONCLUSION: The Young's modulus measurements for the PML muscles were higher at D2; similar results were obtained for the AML muscles. The changes in tightness due to fatigue was thought to be the cause. This hypothesis must be examined in a future study. However, this shows that muscle stiffness changes do not occur only in the PML, and measurement of the AML should also be added to the medical evaluation.

SURVEY OF THE ACTUAL CONDITION OF ACUPUNCTURE AND ADVERSE EVENTS OF MARATHON RUNNERS

KONDO, H.1, FUJIMOTO, H.2, KANEKO, Y.3, IZUMI, S.4, SAKURABA, H.1, YOSHIDA, N.5, YOSHIDA, Y.6, IKEMUNE, S.5, TORIUMI, T.7, TAMACHI, M.3, FURUYA, E.3

1: TSUKUBA U. OF TECH., 2: TOKYO ARIAKE U. OF MED. & HEALTH SCI., 3: KURETAKE COL. OF MED. ARTS & SCI., 4: HOSEI U., 5: TEIKYO HEISEI U., 6: MEIJI U. OF INTEGR. MED., 7: TOKYO COL. OF MED. SPORTS

INTRODUCTION:Acupuncture is a traditional medicine that has been used to treat multiple medical conditions for ancient times and is one of the most popular Complementary and alternative medicine applied in Western medical. Recently, in Japan, peoples interests in health and sports are rising, and marathoners are on the rise. In Japan, Acupuncture therapy is used as one of the treatments and care of sports disorders, but there are very few clear reports on the actual situation. The purpose of this study is to clarify the use situation of acupuncture of marathon runners and adverse events of acupuncture.
METHODS: Design: Cross-sectional questionnaire-based study. We conducted anonymous questionnaire survey by central location test. Setting: Multiple marathon events venues in Japan. Main outcome measures: respondent attributes, experience and impressions of acupuncture treatment, adverse events in acupuncture. We collected 1310 responses. We extracted runners (n = 313) who received acupuncture and totalized.
RESULTS: The reason for receiving acupuncture with the largest was reduction of pain 70.6%, followed in order by relaxation of muscle tone 43.1%. The body part of treatment with the largest proportion of responses was Low back at 47.9%. 72.5% of the respondents felt the effect of acupuncture. 56.9% of respondents had a positive effect on running. The most proportion of responses adverse event of the acupuncture experienced by the runner was pain when insertion of needles 9.1%, follow in order by pain and discomfort after acupuncture 6.4% and subcutaneous bleeding 6.1%. 2.9% of the runners had experiences that acupuncture had hindered for running.
CONCLUSION: The reason for using acupuncture is the same as the results of previous studies for the general public, with the most reduction of pain. There were few severe adverse events due to acupuncture. Many adverse events were due to side effects of acupuncture. Meanwhile, the number of cases that caused difficulties in running by acupuncture treatment was small. Symptoms related to musculoskeletal pain respond well to acupuncture treatment. There is evidence to support the use of acupuncture for the short-term treatment (Michael 2017). In competitive sports, drug use restrictions are increasing due to the regulation of doping and progress of

examination. Acupuncture is a modality that has significant potential for into the treatment of sports medicine field as few side effects and high safety.

ABDOMINAL MUSCLE THICKNESSES IN HIGH SCHOOL SOCCER PLAYERS

TEJIMA, R., FUKUDA, Y., YAMAGUCHI, T., KOYAMA, K.

TOKYO ARIAKE UNIVERSITY OF MEDICAL AND HEALTH SCIENCE

INTRODUCTION:Low back pain (LBP) is a common musculoskeletal disorder in athletes. A previous study reported that the cross-sectional areas (CSAs) of the lumbar multifidus muscle (LM) of the affected side decreases in patients with unilateral LBP (1). However, our study found that the CSAs of the LM on the non-kicking side was larger in healthy high school soccer players. In addition, the LM cooperates with the abdominal transverse muscle (TrA) and internal oblique muscle (IO) via the thoracolumbar fascia to stabilize the lumbar region. We hypothesized that soccer players have asymmetrical abdominal muscles size (thickness) between the kicking and non-kicking sides. Therefore, here we compared the abdominal muscle thickness between the kicking and non-kicking sides in Japanese high school soccer players.
METHODS: The subjects were 37 healthy high school soccer players. All athletes were ranked at the intra- national level. The thickness of the TrA, IO, and external oblique (EO) abdominal muscles were measured at rest and contraction in the supine position using an ultrasound system. The measurement site was located at the margin of the rib and iliac crest on the anterior axillary line, and the probe was set perpendicular to the anterior axillary line. The measurement at rest was obtained at the end of the resting expiration. The measurement at contraction was obtained when the abdominal retraction motion (draw-in) was performed and abdominis lateral muscle thickness was at the maximum.
RESULTS: There was no significant difference in the thickness of the abdominal muscles at rest between the kicking and non-kicking sides. On the other hand, the thickness of the TrA and IO abdominal muscles were significantly different between the kicking and non-kicking sides during contraction (kicking vs non-kicking sides: TrA, 0.65±0.2 vs 0.70±0.2; IO, 1.32±0.2 vs 1.41±0.3; $p<0.05$).
CONCLUSION: Here, we showed that the thickness of the TrA and IO muscle on the non-kicking side increased during contraction. The asymmetrical muscle thickness may affect the kicking motion. We think that several loads are applied to the trunk of the non-kicking side due to the repetitive kicking motion. A limitation of this study was that it did not consider other parameters, such as electromyography and biomechanical factors, to clarify the relationship of the kicking and non-kicking sides in soccer players. Overall, the muscle thickness of the TrA and IO abdominal muscles on the non-kicking side increased during contraction in Japanese high school soccer players.

EFFECT OF THE SEX CYCLE ON THE RISK OF ANTERIOR CRUCIATE LIGAMENT INJURIES

TAKAHASHI, N.1, SAKURAI, T.1, HAGIWARA, R.1, SAKURAI, R.1, KUBO, Y.1

1 TOKYO ARIAKE UNIVERSITY OF MEDICAL AND HEALTH SCIENCES

INTRODUCTION:Although it is known that sex hormones may be involved in the occurrence of female anterior cruciate ligament (ACL) injuries, it is not yet conclusive [1)]. The follicle hormone is known to be involved in ligament tension and the luteinizing hormone to be involved in muscle hardness; however, there are few reports examining the sex cycle[2)]. It is also reported that considering the menstrual cycle is important in conditioning female athletes[3)].Therefore, this study aims to examine the impact of the sexual cycle on the risk of ACL injuries , both subjectively and from a biomechanical perspective.
METHODS: Twenty subjects were chosen amongst female university students (mean age: 20.8±0.9yrs). Based on their menstrual cycle, we divided them into a normal group (n=12) and an irregular group (n=8). Ovulation clear tests (One Step Ovulation Clear Test Strip: Made by Beauty & Health Research) were used to divide the menstrual cycle into four phases and each phase was compared. To calculate muscle power output, isokinetic knee flexion torque and isometric knee flexion torque were measured. Additionally, muscle fatigue index was calculated from the constant velocity knee flexion stretching torque. Furthermore, counter movement jump and single leg landing trials were conducted as biomechanical elements to calculate the flexion angle of the knee joint, valgus angle, and trunk bending angle. Finally, a questionnaire on menstrual symptoms was used to identify the more subjective conditions of menstruation.
RESULTS: There was no significant difference in muscle output, muscle fatigue degree, and dynamic joint angle between the groups. The questionnaire identified symptoms such as fatigue, abdominal pain, and back pain in both the normal and irregular groups.
CONCLUSION: The results suggest that the sex cycle has no impact on muscle function or biomechanical surface, and hence has no effect on the risk of ACL injuries. However, the questionnaire showed that the subjects' subjective condition were deteriorated during the menstrual period, suggesting that the subjective sensation may have a large influence on exercise performance.

ALTERATIONS IN GRIP POWER AFTER ROTATOR CUFF TEARS IN A RAT MODEL

LIN, Y.J.1, SU, W.R.2

NATIONAL CHENG KUNG UNIVERSITY <1>, NATIONAL CHENG KUNG UNIVERSITY HOSPITAL, COLLEGE OF MEDICINE, NATIONAL CHENG KUNG UNIVERSITY <2>

INTRODUCTION:Rotator cuff (RC) tears are a common clinical problem in overhead athletes and the elderly. It may cause pain and loss of shoulder function. Due to anatomic similarities, numerous rat models are established to study RC injuries. However, as a result of RC

injury, functional changes did not be evaluated in most animal models. Although gait analysis has been used to evaluate forelimb function following RC tears in rat models (1), different loading patterns in quadrupeds were not able to exactly replicate the human shoulder. There is still no widely accepted method for functional assessment in RC tears rat models. Inspired by a hand grip task which activating RC muscles in humans (2), we would like to propose grip power test as a new method of functional evaluation in a rat RC tear model. The aim of this study was to examine the effect of RC tears on grip power in a rat model.
METHODS: Six female Sprague-Dawley rats (450±50 grams) were divided into sham-operated control (n=2) or RC tear (n=4) groups. A unilateral surgery was conducted under general anesthesia, followed by cage activity. Briefly, a longitudinal skin incision was made with blunt dissection down to the deltoid. The deltoid was released with sharp dissection to expose RC muscles with tendons at their bony insertion, followed by primary closure in the sham group without further procedures. In the RC tear group, the tendon of supraspinatus was detached from its bony insertion. For both groups, grip power on the operated side was measured 1 day prior to surgery, and at 7, 14 and 35 days post-surgery, using a grip power meter (BioSeb). To study the within-group effect of time, the grip powers between pre-surgery and post-surgery at each time points were compared using the Wilcoxon signed-rank test. To study difference among groups, change (difference) from pre-surgery was compared between groups at each time point using the Mann-Whitney U test. For all tests, P values < 0.05 were considered significant.
RESULTS: When compared with pre-surgery values, lower grip forces were observed in the RC tear group at all the time points after surgery; however, the difference was non-significant with p=0.068. Grip forces in the sham group were not decreased from the pre-surgery level at all the time points (post-surgery > pre-surgery, p=0.18). Changes from pre-surgery were bigger in the RC tear group than the sham group at all the time points without significant differences (p=0.133).
CONCLUSION: This study demonstrated changes in grip power following RC tears in a rat model. The results indicated that grip forces were decreased with RC tear despite a lack of statistical significance. The present findings suggested the potential of grip power test for being a new method of functional assessment in an RC tear rat model.

ASSESSMENT OF LUMBAR DEFORMATION IN SURFER

NOGAMI, Y., HORIKOSHI, T.
SHONAN INSTITUTE OF TECHNOLOGY

INTRODUCTION:Surfing is a major recreational sport and many people enjoyed all over the world. In 2020, surfing was adopted the official event of the Tokyo Olympic games. Some previous studies have shown that surfer has many external injuries. Additionally, acute and chronic lumbar pain are sever problem in surfers. The purpose of this study was to evaluate the degree of lumbar deformation and clarify the mechanism of causing lumbar pain in surfer.
METHODS: Six healthy active surfer and 6 healthy sedentary were enrolled in this study. In surfing group, inclusion criteria were over 2 years surfing history. Sedentary have no back problems. We measured star excursion balance test (SEBT), one leg standing with eyes closed, standing broad jump test, toe muscle strength, and lumbar alignment. Lumbar alignment was assessed by the distance in the vertical direction from the celling line was measured at the 2nd and 3rd lumbar vertebrae (L2 and L3).
RESULTS: Surfers age were 21 ± 1.7 years and age-matched sedentary group (22 ± 0.6 years). Mean surfing history was 56 ± 66 months. All SEBT (anterior, posteromedial, and posterolateral) were not significantly difference between both groups. One leg standing with eyes closed time in dominant was not significantly difference between surfing and sedentary groups (24 ± 27 vs. 16 ± 10 sec, n.s.). Additionally, these following indices did not show any significant difference: standing broad jump test (204 ± 13 vs. 170 ± 38 cm, n.s.), toe muscle strength (R; 25 ± 11 vs. 21 ± 4 kg, L; 21 ± 5 vs. 21 ± 10 kg, n.s.) . However, lumbar curvature in surfing group was significantly straight compare to sedentary group (1.9 ± 0.9 vs. 4.3 ± 1.0 cm, P = 0.03).
CONCLUSION: In surfing group, there were no significantly difference from sedentary group in SEBT, one leg standing with eyes closed, toe muscle strength and so on. The lumbar vertebrae became straight in surfing group clearly compared to sedentary. These results were shown that the high risk of developing low back pain. Consequently, there is a risk the performance may be degraded in the future.

THE IMPACT OF PERIPHERAL VISION IN SOCCER

OLM, T., BASKIN, K., HERDE, K.
TALLINN UNIVERSITY

INTRODUCTION:Most professional soccer players have similar high characteristics of aerobic and anaerobic working capacities. Therefore, today more often the state of the perceptual-cognitive systems turns out to be the crucial factor for victory. In sports, which are dynamic and involve rapidly moving information sources, perfect visual perception is necessary. The aim of this study is to examine peripheral vision (PV) in soccer players of different ages and field positions.
METHODS: The subjects were 271 players of the best clubs of Estonia. The athletes were divided into 3 age and 4 role groups. The first age group (n=205) consisted of players aged 17 to 21 (average 19.9±1.74), the second group (n=40) contained players aged 22 to 26 years (average 24.9±0.79) and the third group (n=26) contained players aged 27 to 31 years (average 28.8 ±1.28). PV was measured by perimeter (8 meridians). All the test battery included anthropometrics, ECHO and ECG, BLa concentration, VO2max and the anaerobic threshold were recorded. The simple and choice reaction times were measured before and after treadmill test. The ANOVA-test was used. Statistical significance was assumed at P<0,05. Pearson product moment correlation coefficients were calculated.
RESULTS: The examined soccer players visual field extended to 92.9° laterally, 46.7° medially, 57.5° superiorly and 76.3° inferiorly. The comparison of the data of soccer players of different ages showed that PV was best in the second age group (average 23.9). From the four role groups the best indices were in strikers, followed by midfielders and defenders. The indices were lowest in the goalkeepers' group. The mean values of age and role groups did not differ significantly. Correlation analysis shows that there is no relationship between PV and other organ systems except the nervous system. The indices of PV have a strong negative correlation (at the 0.01 level) with the simple reaction time and a moderate one (at the 0,05 level) with the choice reaction time.
CONCLUSION: We can assure that all our players had a good or very good peripheral vision. A wider field of view provides an opportunity for better peripheral awareness, which accelerates the decision-making and helps to prevent collision (1). There are many contradictory investigations about the influence of age and the positional role (2). Our results show that peripheral vision tends to improve until the thirties. Although from the results we can conclude only a tendency to differ, we are sure that different field positions require different

characteristics of vision on different levels. The diminution of the differences between the positional role groups might be due to frequent role changes, especially at young ages.

HINDFOOT ENDOSCOPIC SURGERY FOR POSTERIOR ANKLE IMPINGEMENT SYNDROME IN BALLET DANCERS: COMPARING THE OUTCOMES OF UNILATERAL AND BILATERAL SURGERY

HOJO, T., MAKI, M., KIDO, M., HARA, Y., IMAI, K., OHASHI, S., YAMAMOTO, H., TACHIBANA, M., IKOMA, K.
DOSHISHA UNIVERSITY

INTRODUCTION:To compare the outcome of unilateral versus bilateral simultaneous endoscopic surgery for posterior ankle impingement syndrome (PAIS) in ballet dancers and to examine the usefulness of bilateral simultaneous surgery.
METHODS: The patients were 22 females with PAIS. We compared the surgical time, Japanese Society for Surgery of the Foot, Ankle and Hindfoot scale (JSSF) scores, and Visual Analog Scale (VAS) scores before and after surgery, and the return time to preoperative sports activities between bilateral simultaneous surgery (bilateral group; 4 cases and 8 feet) and unilateral surgery (unilateral group; 18 cases and 20 feet).
RESULTS: Mean operation time was 49.2 minutes in the unilateral group and 98.8 minutes in the bilateral group. In both groups, the JSSF score significantly improved, as follows: from 71.6 points before surgery to 99.5 points at final follow-up in the unilateral group, and from 74.8 points before surgery to 98.8 points at final follow-up in the bilateral group. In both groups, the VAS score significantly decreased, as follows: from 66.7 mm before the operation to 8.0 mm at final follow-up in the unilateral group and from 72.1 mm before the operation to 1.3 mm at final follow-up in the bilateral group. The duration until return to the preoperative sports activities was 4.8 weeks in the unilateral group and 9.0 weeks in the bilateral group, with no significant difference between the groups.
CONCLUSION: Bilateral simultaneous surgery for bilateral posterior ankle impingement syndrome in ballet dancers would be useful.

SURVEY ON THE ADVERSE EVENTS OF ACUPUNCTURE AND MOXIBUSTION FOR ATHLETES IN JAPAN

FUJIMOTO, H.1, KONDO, H.2, KANEKO, Y.3, IZUMI, S.4, SAKURABA, H.2, YOSHIDA, N.5, YOSHIDA, Y.6, IKEMUNE, S.5, TORIUMI, T.7, TAMACHI, M.8, FURUYA, E.3
1: TOKYO ARIAKE UNIVERSITY OF MEDICAL AND HEALTH SCIENCES 2: NATIONAL UNIVERSITY CORPORATION OF TSUKUBA UNIVERSITY OF TECHNOLOGY 3: KURETAKE COLLEGE OF MEDICAL ARTS AND

INTRODUCTION:Acupuncture and moxibustion is one of the traditional medical therapies. The efficacy of acupuncture and moxibustion in sports medicine has been reported (Michael, 2017), but its adverse events in athletes are still unreported. The purpose of this cross-sectional questionnaire-based study is to investigate the challenges that interfere with the adverse event and sports activities by the acupuncture and moxibustion to an athlete.
METHODS: Design : Cross-sectional questionnaire-based study. In total, 1804 subjects, including marathon convention entry athletes and university athletes were enrolled in this study. The survey was conducted by distributing the questionnaire or via online questionnaire to the athletes who fit the criteria for the study. The questionnaires were collected after consent was received from the participants; online questionnaires were also collected. The questionnaire were examined for age, sex, content of adverse event, experience of interfering with sports activities, presence of adverse events due to acupuncture and moxibustion.
RESULTS: In total, 1525 (84.5%) valid responses to the questionnaires were received. The survey analyzed 841subjects (55.1%, Male: 603, Female: 234, unanswered: 3) who experienced acupuncture and moxibustion . The following responses about adverse events of acupuncture were obtained: "pain at time of needle insertion": 143 (16.6%), "subcutaneous-bleeding": 85 (9.8%) and "pain and feel heavy due to the needle": 85 (9.8%), among others. For moxibustion, responses included "burns": 33 (3.9%) and "malaise": 32 (3.8%), among others. In total, 282 subjects experienced adverse events (33.5%), 438 did not experience any adverse events (52.0%), and in 121, the causes were unknown (14.3%). For the subjects who experienced adverse events, the strength of the needle stimulus was categorized as: "very strong": 19 (6.7%), "strong": 73 (25.8%), "moderate": 167 (59.1%), and "weak": 23 (8.1%). The adverse events interfered with sports activities in 487 (65.5%) subjects and in 252 (34.4%), it did not cause trouble. The strengths of needle stimulus in the subjects who reported interference with sports activities were "very strong": 15 (5.9%), "strong": 56 (22.2%), "moderate": 156 (61.9%), and "weak": 25 (9.9%). The strengths of needle stimulus in the subjects who did not report any interference with sports activities were "very strong": 4 (0.8%), "strong": 72 (14.7%), "moderate": 348 (71.4%), and "weak": 63 (12.9%).
CONCLUSION: In a prospective studies, adverse events of acupuncture and moxibustion have been reported to be caused by strong stimulation (Furuse, 2017). Even in this study targeting athletes, adverse events of acupuncture and moxibustion tend to occur when the stimulation sense is strong. It was suggested that acupuncture sensation may be one of the factors of adverse events in sports activities.

EFFECTS OF LOW-INTENSITY HIGH-REPETITION RESISTANCE EXERCISE(LIHRRE) ON GLYCATED HEMOGLOBIN(HBA1C) AND INSULIN RESISTANCE IN ELDERLY WOMEN WITH TYPE 2 DIABETES MELLITUS(T2DM)

KIM, S.
NATIONAL INCHEON UNIVERSITY

Type 2 diabetes is a worldwide increasing trend and one of death worldwide. As the age increases, prevalence of diabetes in elderly women is increasing more than other age groups. Also, there is a greater risk of muscle loss in elderly women with type 2 diabetes. Resistance exercise is known to be effective in preventing muscle loss. Therefore, the purpose of this study was to investigate the effects of low-intensity high-repetition resistance exercise(LIHRRE) on glycated hemoglobin(HbA1c) and insulin resistance in elderly women with type 2 diabetes mellitus(T2DM). Nine elderly women with T2DM were randomly assigned to low-intensity high-repetition resistance exercise group(LIHRRE, n=5), and control group (CON, n=4). Elderly women with T2DM in LIHRRE trained at 30% of 1RM, 3 sets of six actions, 60 minutes a day, 3 times a week, for 12 weeks. HbA1c was measured Afinion AS 100 and the insulin resistance was measured by the enzyme-linked immunosorbent assay kit(ELISA kit). No statistically significant between-group or group-by-time interactions were observed. low-intensity high-repetition resistance exercise(LIHRRE) failed to improve on glycated hemoglobin(HbA1c) and insulin resistance in elderly women with type 2 diabetes mellitus(T2DM). In conclusion, we do not recommend low-intensity high-repetition resistance exercise(LIHRRE) during the 12-week period and recommend moderate to high-intensity resistance exercise for effects of improving glycated hemoglobin(HbA1c) and insulin resistance within 12 weeks.

17B-ESTRADIOL HAS A POSITIVE EFFECT ON REPAIR OF SKELETAL MUSCLE INJURY

TAKINO, A., HIROSE, T., SAKURAI, T.

TOIN UNIVERSITY OF YOKOHAMA

INTRODUCTION:Estrogen decrease has been associated with a number of negative outcomes, including a greater incidence of injury as well as a delay in recovery from these injuries. In recent year, our understanding of the protective effects of estrogen against various types of injury and disease states has grown immensely. Estrogen may affect muscle damage and inflammation, but the physiological significance of this, particularly potential effects on muscle repair and recovery in humans, and the mechanisms of its actions are as of yet unknown. Therefore, in this study, we observed the influence of estrogen on inflammation and repair process of skeletal muscle over time.
METHODS: Female wistar rats (14 weeks old : n=54) were divided into four groups : control (C, n=9), sham (Sham, n=9), ovariectomized (OVX, n=15) and ovariectomized + estrogen (0.25 mg pellet) (OVX+E, n=16). After 10 days of estrogen exposure, were muscle injured with a 0.5% Bupivacaine Hydrochloride (BPVC). Tibialis anterior muscle were removed 3, 5 and 7 day post-injury and western blotting for Calpain 3, heat shock protein (HSP70), activated (Pax7) and fusion (MyoD) satellite cells.
RESULTS: Injury skeletal muscle showed elevated muscle calpain 3 activity after muscle injury compared to intact muscle. HSP70 induction in skeletal muscle injuries was greater in C rats and OVX+E rats than OVX rats at the level of protein ($P<0.05$, $P<0.005$). Pax7 and MyoD expression served to define satellite cell activation and proliferation and were found to be up-regulated by estrogen ($P<0.05$).
CONCLUSION: These findings indicate that the gender-specific HSP70 and satellite cell response to skeletal muscle injury is mediated by the female-specific hormone estrogen.

THE USE OF ACUPUNCTURE IN ATHLETES OF INDIVIDUAL SPORTS AND TEAM SPORTS IN JAPAN

KANEKO, Y., FUJIMOTO, H., KONDO, H., SAKURABA, H., IZUMI, S., YOSHIDA, N., IKEMUNE, S., YOSHIDA, Y., TORIUMI, T., TAMACHI, M., FURUYA, E.

KURETAKE COLLEGE OF MEDICAL ARTS AND SCIENCES

INTRODUCTION:Acupuncture has become the most widely-used complementary and alternative medical procedures, based on a growing number of clinical trials and systematic reviews (Hempel et al., 2014). The literature showed its effectiveness for pain (Vickers et al., 2012). On the other hand, many athletes in Japan receive acupuncture while it is yet unclear whether acupuncture is effective for sports-related injuries and disorders. The aim of this study is to investigate the use of acupuncture across different type of sports.
METHODS: We conducted anonymous questionnaire survey at multiple setting. Athletes were divided into individual sport group (IG) and team sport group (TG). They were asked; experience of acupuncture, the purpose of receiving acupuncture, parts of body they had any pain, positive/negative effect of acupuncture for their performance. We extracted athletes who have an experience to receive acupuncture and compared the difference of responses between IG and TG.
RESULTS: We collected 1525 responses and extracted 716 for IG and 290 for TG who had an experience of acupuncture. The most common purpose of receiving acupuncture was reduction of pain in IG (71.4%) as well as in TG (72.1%) followed by relaxing muscle tightness (IG: 44.4%, TG: 41.4%), hastening recovery (35.9%, 32.1%), conditioning (21.2%, 13.4%), prevention of injuries (11.3%, 4.5%), improving ROM (8.4%, 4.8%) and rehabilitation (5.2%, 6.2%). There was a significant difference in proportion of the purpose between the groups ($p<0.05$). Both group complained of a low back pain at most (IG: 30.6%, TG: 31.4%) and a knee pain (22.5%, 25.2%) as the second. 33.4% of IG and 21.4% of TG felt a certain positive effect, and 25.8% of IG and 33.4% of TG felt a somewhat positive effect of acupuncture for their performance while 1.0% of IG and 1.4% of TG felt a negative effect. There was a significant difference between the groups in the positive effect ($p<0.05$). 32.8% of IG have experienced acupuncture more than 10 times though 33.4% of TG had 2-5 times at most of each group and there was a significant difference ($p<0.05$).
CONCLUSION: Our investigation showed the most common purpose of receiving acupuncture in athletes was reduction of pain. The proportion of the purpose, the positive effect, and the frequency of receiving acupuncture were different between IG and TG while their complaint of pain was similar and the negative effect was relatively few in both groups. It is considered that these differences were due to the characteristics of each sport. It was remarkable that they received acupuncture not only for pain but also for other purposes. The present study only showed subjective effect of acupuncture, but it could be related to an ergogenic effect of acupuncture in sports (Ahmedov, 2010). It is concluded that acupuncture might have potential as a doping-free modality to help athletes in different conditions for better performance.

EFFECT OF COMBINED AEROBIC AND CORE MUSCLE TRAINING PROGRAMS ON POSTPARTUM FITNESS, LOW BACK PAIN AND PELVIC FLOOR PROBLEMS

CHEN, C.Y., WU, W.L., LIANG, J.M., WANG, M.L., LIAW, L.J., HSU, H.T.

KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION:A recent literature (Østbye et al., 2012) showed that 56% of postpartum women retain up to 5 kg weight, and 13% retain 5–10 kg in a year after delivery. Thus, the issues related to postpartum weight loss are important for postpartum women. The benefits of aerobic exercise for weight control has been confirmed in past studies (Mottola., 2009; Lim et al., 2015). Core training is also a suitable exercise for postpartum women to enhance their physical fitness, improve core stability and core strength. Therefore, this study investigated how the training exercises combined both core and aerobic affect the body composition, core stability, and back/pelvic health of postpartum females.
METHODS: Thirty-five females aged 33.1 ± 4.1 years, postpartum 130.9 ± 52.9 days participated in the 12-week exercise program, twice a week, an hour each session. In the first six weeks, core-strength exercise was arranged, and aerobic exercise was performed during the last six-week courses. Both core and aerobics exercises contain 5-10 minutes of warm-up and relaxation exercises, 30-40 minutes of the main exercise. Each subject required to complete the "Roland-Morris Low Back Pain Disability", "Pelvic Girdle Pain", and "Pelvic Floor Distress Inventory" questionnaires before and after participating in the course. Moreover, physical fitness, including body composition and core muscle strength/endurance was also evaluated before and after 12-week exercise courses.

RESULTS: It showed a significant reduction in body fat percentage after training (p=0.017) and a significant improvement in the core muscle strength/endurance, presenting results in V-sit test (p=0.012) and the double-leg-lowering test (p=0.066). Furthermore, it reported a significantly lower scores in the pelvic girdle pain (p=0.068) and pelvic floor distress (p=0.043) after training.
CONCLUSION: The results of the study showed that this postpartum exercise program help reduce body fat, improve core muscular endurance and pelvic floor problems. Hence, implementation of this 12-week combined training program is feasible for postpartum women.

CHANGE OF BONE STRUCTURE RELATIVE TO THE CHRONOLOGICAL AGE AND BIOLOGICAL MATURATION IN ADOLESCENT MALE ATHLETES

UTCZÁS, K., TRÓZNAI, ZS., KALABISKA, I., PETRIDIS, L.

UNIVERSITY OF PHYSICAL EDUCATION

INTRODUCTION:One of the most marked changes during puberty is well reflected on the skeletal system; when there is spurt in growth viewed by the timing in peak height velocity (PHV). Changes during this period are demonstrated not only on bone size, but also on bone structure. However, maximal growth velocity in bone mass and in bone mineral density (BMD) occurs usually few months after PHV. The purpose of this study was to examine changes in skeletal maturation during puberty relative to PHV in adolescent male athletes.
METHODS: 212 male participants were measured from 12 to 16 years coming from various sports (soccer, handball, basketball, modern pentathlon, wrestling, biking, kayaking). Basic anthropometric measures were taken with standard measurement technique. Skeletal status was assessed using a DEXA (Lunar Prodigy), and bone age was estimated by ultrasound method (Sunlight BoneAge). PHV and age at PHV (APHV) was estimated from anthropometric measures. Participants were then divided into groups according to their PHV status (pre-PHV, in-PHV, post-PHV) and according to their skeletal age (less matured, normal, more matured).
RESULTS: Mean APHV of the examined sample was 13.5±0.6 years. Mean values of BMD for the pre-PHV, in-PHV, and post-PHV groups were 0.99±0.06, 1.07±0.07, and 1.22±0.07 g/cm2 respectively. A slower rate in BMD increase before PHV and a faster rate after PHV was noticed. Significant differences were found in body dimensions and in BMD between groups of different skeletal maturation, however, the magnitude of differences varied according to PHV status; differences were more profound within the in-PHV group. In the pre-PHV and in the in-PHV groups skeletally less matured athletes had lower mean values for BMD Z-scores compared to normal and more matured athletes, however, in the in-PHV group this values was even below the critical value of -1 (-1.08).
CONCLUSION: Growth in BMD showed similar trends in the examined athletes with that of average children. Slower rate in bone structure maturation before and within PHV results in many cases to negative values in the BMD Z-scores. This also means, that in the interpretation of bone density PHV and skeletal maturation status should also be considered. This information can be useful to coaches and practitioners for training load optimization and injury prevention.

FOOT GROWTH CHARACTERISTICS OF NEPALE MAJOR ETHNIC GROUPS CHILDREN AGED 5-16 YEARS

UEDA, K.1, KOKUDO, S.2, DEVKOTA, B.3, NAKANO, T.4, SAGAWA, T.5

1 MINATOGAWA COLLEGE, 2 KOBE UNIVERSITY, 3 TRIBHUVAN UNIVERSITY, 4 NAGOYA GAKUIN UNIVERSITY, 5 KANAZAWA UNIVERSITY

INTRODUCTION:The foot status of children is influenced many factors such as heredity and environment. It is assumed that the Nepal geographical condition such as hill or mountain environment affects the growth status. Additionally, The heredity status also quite different among ethnic groups (EG) such as Brahman/Chhetri (B/C) and Janajati (JAN). This study was aimed to investigate foot growth characteristics of B/C and JAN children at Nepal hill area.
METHODS: The samples were 1,272 healthy children of B/C at urban area and JAN at rural area (574 boys and 698 girls) aged 5-16 years, higher secondary school in/around Kathmandu Valley, Nepal. Foot sole parameters, foot length, width, width/length ratio, arch type, were measured using a 2D foot scanner during 2015-2018. Their height and weight were also measured. Descriptive statistics of foot sole parameters, height and weight were calculated by age, sex and ethnic groups (B/C and JAN). The difference of these statistics was compared between ethnic groups by age and sex.
RESULTS: Mean foot length of 5-yr of age was 16.4-17.9cm. It reached 19.2-20.2cm at 9-yr of age. There was no significant difference of foot length between B/C and JAN till 10-yr of age for boys and 6-yr of age for girls. However, the foot length of BC was significantly($p<0.05$) larger than that of JAN from 11-yr of age for boys and 7, 9-yr for girls. The mean foot length at 15-yr of age was 24.6cm for B/C boys, 23.3cm for JAN boys, 21.7cm for B/C girls and 22.3cm for JAN girls. Mean foot width of 5-yr of age was 6.5-6.7cm. It reached 7.7-7.8cm at 10-yr of age. There was no significant difference of foot width between EG except 11-yr, 14-yr girls. It seemed that foot growth, especially foot length was different between EG; foot length of B/C was larger than that of JAN after adolescence. We found the height differences between EG on 14-yr boys and 7,9 and 13-yr girls. However, the ethnic difference was smaller than foot length. It seemed that growth difference of EG was appeared clearly on the foot size after growth spurt.
Regarding foot arch, 6.6% of children was flat, 76.4% was normal, 14.0% was high and 6.6% was very high. There was no difference for arch type appearance between EG (chi-square=2.77 for boys and 7.76 for girls). Nepalese children have a high rate of normal arch, since flat arch was 7.2%, normal (normal + high) was 80.7%, and very high was 12.1% on Japanese children (Mimura et.al, 2010). It was significantly different between Nepalese and Japanese (chi-square=37.93, $p<0.01$).
CONCLUSION: The foot length of BC children is larger than JAN children after growth spurt. There is no difference of foot arch construction rate between JAN and B/C; however, their normal rate is higher than Japanese children.

THE ASSOCIATION OF HIP STRENGTH, FLEXIBILITY AND PELVIC TILT WITH A PAST HISTORY OF GROIN PAIN IN MALE FOOTBALL PLAYERS

NAOTO, N.

HOSEI UNIVERSITY

INTRODUCTION:Groin pain is common injury in football players. Hip / groin strength and flexibility tests are commonly performed to detect players with the risk factors for groin pain (1). In addition, it is a possibility that pelvic tilt is a potential risk factor for groin pain. However, it has not been clarified. So, the purpose of this study was to examine whether hip / groin strength and flexibility tests and pelvic tilt are associated with a past history of groin pain.
METHODS: 28 Male football players completed questionnaire, hip/groin strength (flexion, extension, adduction, abduction) were measured by a handheld dynamometer with external belt-fixation. Hip / groin flexibility (modified Thomas test, Straight leg raise test, modified Ober test, bent knee fall out test) were measured by an universal goniometer and a bubble inclinometer. Standing pelvic tilt was measured by a Palpation Meter. Standing pelvic tilt was determined as angle formed by a horizontal line drawn between anterior superior and posterior superior iliac spines. Positive degrees were used to describe anterior pelvic tilt, while negative degrees were used to describe posterior pelvic tilts in the sagittal plane.
RESULTS: There were 9 players with previous groin pain leading to time-loss from training and / or match play (5 dominant side groin pains; D-GP, 7 non-dominant side groin pains; ND-GP). Hip strength tests were not associated with previous groin pain. We found that the angle of hip flexion during modified Thomas test had significant difference between the control group (3.5±6.7°) and the D-GP group (11.3±5.6°; p=0.023, Cohen's d=1.19). Also, the ND-GP group had the decreased anterior pelvic tilt compared with the control group (p=0.086, Cohen's d=0.79).
CONCLUSION: Male football players with a past history of groin pain on dominant side had decrease of hip flexion angle during modified Thomas test. Players with previous groin pain on non-dominant side had decrease of anterior pelvic tilt by compared with non-groin pain players.

THE CHARACTERISTICS OF PHYSICAL ACTIVITY LEVELS IN KOREAN CANCER SURVIVORS: KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATIONS SURVEY, 2014-2016

LEE, J.1, MIN, J.1, KANG, D.3, JEON, J.1,3,4

SPORTS INDUSTRY STUDIES, YONSEI UNIVERSITY

INTRODUCTION:The purpose of this study is to examine physical activity (PA) levels of the cancer survivors to compare with non-cancer diagnosis individuals using propensity score matching (PSM) analysis.
METHODS: We used data from 2014-2016 Korean National Health and Nutrition Examination Surveys (KNHANES) including 646 cancer survivors and 15,352 non-cancer diagnosis individuals and PA levels were measured with self-reported. To better compare the PA levels between the groups, 646 non-cancer diagnosis individuals were selected through the 1:1 propensity score matching by sex and ages.
RESULTS: The most common cancer type was gastric (24.4%), breast (15.9%), Cervical (14.8%) and colorectal (12.1%) among cancer survivors. Cancer survivors were significantly lower in moderate work PA (p=0.006), both moderate and vigorous leisure-time PA (p=<0.001 for both), moderate-to-vigorous PA (p<0.001) and total PA (p<0.001) compared to non-cancer diagnosis individuals. Moreover, cancer diagnosis individuals' participation rate of meeting ACSM guideline were 83% (OR= 0.17, 95% CI=0.13-0.22; p<0.001), total PA were 70% (OR = 0.29, 95% CI=0.23-0.38; p<0.001), moderate to vigorous PA were 92% (OR = 0.08, 95% CI=0.06-0.10; p<0.001), work PA were 71% (OR = 0.29, 95% CI=0.21-0.41; p<0.001) and leisure-time PA were 96% (OR = 0.14, 95% CI=0.11-0.18; p<0.001) lower compared to non-cancer diagnosis individuals.
CONCLUSION: Individuals who had diagnosed cancer are participate lower levels of PA than those who have never had cancer.

CHANGES IN PERCEPTUAL AND PERFORMANCE DURING A PERIOD OF FLUID RESTRICTION IN TEAM SPORT ATHLETES DURING PRE-SEASON TRAINING IN COOL ENVIRONMENTAL CONDITIONS

BARGH, M., KING, R., JONES, R.

UNIVERSITY OF LINCOLN

INTRODUCTION:During competitive match-play in team sports played in cool environmental conditions where sweat rates are low, the physiological need to concurrently ingest fluid should, theoretically, be trivial for performance. Regardless of this, fluid ingestion in excess of physiological needs are often observed (Bargh et al., 2016). Restricting fluid ingestion has however previously been found to impact team sport performance in a way which may be attributed to negative perceptual associations (e.g., increased RPE and thirst sensation), rather than exercise induced dehydration per se (Sawka & Noakes, 2007). An attractive strategy may therefore be to lower the accessibility of fluid during training to familiarise individuals with the associated negative perceptions (e.g. thirst, RPE and mouth dryness) and avoid drinking in excess of physiological needs. This study therefore aimed to exam the effects of a four-week familiarisation to fluid restriction, on fluid restricted exercise performance, perceptual responses and fluid balance.
METHODS: 12 rugby league players completed a field-based training session followed by a 1.2k shuttle run (1.2KSRT) in fluid restricted conditions at pre- and post-intervention. Body mass, thirst sensation, mouth dryness and rating of perceived exertion (RPE) were measured. Fluid intake post-training (1-hour) was recorded and urine samples were collected (3 x per week) to assess hydration status (UOsm) and drinking behaviour. Players completed a four-week intervention with either; No fluid (NF; n = 6, age 17 ± 1yrs, height 180.0 ± 6.1cm, body mass 93.5 ± 12.2kg) or habitual ad libitum fluid intake (FI; n = 6, age 18 ± 1yrs, height 179.1 ± 7.6cm, body mass 87.5 ± 13.8kg) during field-based training sessions (2 ± 1 per week).
RESULTS: Compared with FI, NF had a trivial effect on 1.2KSRT (0.7%; ±6.0% reduction in time to completion), Δmouth dryness (0.15 mm; ±2.32%) and RPE (training; -0.12; ±1.85%. 1.2KSRT; -0.39; ±1.04%). NF had a moderate effect on Δthirst sensation (1.58 (AU); ±1.23%). NF had a large mean effect on fluid intake post-training (469; ±214g greater than FI) but a small effect on UOsm (-63; ±109mOsmol·kg-1 less of an increase).
CONCLUSION: In conclusion, four weeks of familiarisation with fluid restriction did not alter 1.2KSRT and perceptual responses to fluid deprived conditions. However, given that no delirious effects on performance, perceptions or fluid balance were observed, in addition to encouraging influences on drinking behaviours post-training, less focus on provision of fluid during training may prove an effective strategy for coaches to restrict occurrences of over-drinking and maximise training time.

EPIDEMIOLOGY OF UNIVERSITY MEN'S SOCCER TEAM INJURIES FOR A YEAR

YUKI, H.

HOSEI UNIVERSITY

INTRODUCTION:In recent years the concept of preventive medicine also penetrated into the football world of Japan, and along with it, injury investigation which is the first step of injury prevention is carried out. However, there is little survey in college football showing high level with the development of J League. Furthermore, since there are few studies carried out by the definition indicated by FIFA, it is difficult to objectively compare even if injury survey is conducted on the team.
Therefore, in this research, in order to prevent injuries, by conducting an injury survey using unified standards worldwide, we can extract the mechanism of injuries occurred in Japanese university football and grasp the actual condition more clearly
METHODS: We investigated and examined injuries occurred in the season of the target team using the method of injury survey recommended by methods of FIFA. The survey items are number of injuries occurrence / occurrence rate (1000 player-hours), classification by trauma / injury / practice / game, by cause of occurrence, by site of injury, by type of injury, by severity, by position, by grade is there. And I analyzed some of them by month.
RESULTS: Many items, such as the incidence of injuries and the number of incidents occurred, were almost the same as those of previous studies1). Under such circumstances, what was unique in this study was the peak number of injuries occurring by month, the first time in May to July when looking at the number of injuries occurred in the game. In addition, in the team of the subject is doing the morning practice from 7 oclock in the class period, in the morning practice, a difference occurs in injury incidence between the school year, significantly first-year university compared to the sophomore Resulted in a small number of injuries.
CONCLUSION: Game schedule becomes overcrowded in Japanese university football
From May to July, it was suggested that special care should be taken at this time because a lot of injuries occur due to a heavy load on the players body.It is reported that the incidence of injury increases when the game schedule becomes overcrowded even in previous research.
In addition, as a reason why the injury of the first grader in the morning practice was small, the first grader of the university has woken up about an hour earlier than the other graduates because of cleaning inside the dormitory. I believe that this difference made a difference in the number of injuries occurring during the grade.
Therefore, even though the wake-up time is early in morning practice, I slept as soon as possible and I thought that getting up as soon as possible was important for preventing injuries.

CHALLENGE FOR THE DEVELOPMENT OF NEW MEDICAL AND PHYSICAL CHECK METHODS FOR EVALUATING ATHLETES MUSCULOSKELETAL DISORDERS AND MOTOR FUNCTIONS

MIYACHI, H.

KYOTO INSTITUTE OF TECHNOLOGY

INTRODUCTION:For athletes, Early detection of musculoskeletal disorders is very important. But, its sometimes too late when they noticed the pain. Therefore, it is better for athletes to have regular check such as musculoskeletal disorders and motor functions. However, conventional check methods require experts such as orthopedic surgeons and physical therapists. In addition, special devices such as echography and Biodex are so expensive that the medical check cannot be easily performed. So, in this research, we developed new check methods which can be easily performed by non-experts, compared the result of conventional check methods with the result of new check methods, and examined validity of new methods.
METHODS: The subjects of this study are 56 healthy male and female athletes aged 8 to 15 years. Orthopedic surgeons performed medical checks such as echography and stress tests. Physical therapists performed physical checks such as measurements of range of motion, physical fitness test and muscular strength measurements. Trainers performed new checks. We compared the result of conventional check methods with the result of new check methods.
RESULTS: As a result of statistics, we found some new check methods related to conventional check methods. We describe below remarkable check methods. First, regarding upper limbs, the shoulder mobility test was related to the measurements of shoulder range of motion. The wall push test was related to the result of the stress test of elbows. Secondly, regarding lower limbs, the active SLR test was related to the diagnosis of Achilles tendonitis. The crouching test was related to the measurements of leg range of motion. The frog test (functional measurement test of legs) was related to leg range of motion and muscular strength of the lower limbs. Finally, regarding trunk of the body, the rotary stability test was related to muscular strength.
CONCLUSION: From the results of this study, it was suggested that some of new check methods are valid as a substitute for conventional medical and physical check methods. First, it was suggested that the active SLR test and the wall push test were valid as a substitute for medical checks. Next, it was suggested that the frog test, the crouching test and the active SLR test were valid as a substitute for measurements of range of motion. Finally, it was suggested that the frog test and the rotary stability test were valid as a substitute for muscular strength measurements. From the above, we suggest that the new check methods is useful as non-experts evaluation. However, there is a possibility that the muscle mass was not enough because the athlete targeted in this study was young from 8 to 15 years old. So it is necessary to check the sports athletes of various ages and to increase the relevance.

PREVALENCE OF KNEE OSTEOARTHRITIS AND CARDIORESPIRATORY FITNESS AND IN JAPANESE MEN AND WOMEN: WASEDAS HEALTH STUDY

IIZUKA, S., SAWADA, S., KAWKAMI, R., TANISAWA, K., TABATA, H., NAKAMURA, N., KONISHI, M., ITO, T., USUI, C., MIDORIKAWA, T., HIGUCHI, M., SUZUKI, K., SAKAMOTO, S., ISHII, K., OKA, K., TORII, S.

WASEDA UNIVERSITY

INTRODUCTION:Knee osteoarthritis is a major disability of elderly people, especially for older women. However, limited data are available on the relationship between knee osteoarthritis and cardiorespiratory fitness among Japanese men and women. This cross-sectional study is to investigate the relationship between cardiorespiratory fitness and the prevalence of knee osteoarthritis among Japanese men and women in WASEDAS Health Study
METHODS: WASEDAS Health Study is a cohort study which was launched in 2014. We used a part of the baseline data in this study. Participants of this study were 633 Japanese men [median (IQR) age 56 (48-65) years] and 307 women [median (IQR) age 50 (45-57) years] who completed a medical examination, maximal exercise test. The participants were divided into quartiles based on cardiorespiratory

fitness. The prevalence of knee osteoarthritis were based on self-reports from questionnaires. Odds ratios and 95% confidence intervals for the prevalence of knee osteoarthritis were obtained using logistic regression models while adjusting for sex (male/female), age (continuous variable), body mass index (continuous variable), and physical activity (yes/no).
RESULTS: 21 participants had knee osteoarthritis. Using the 1st quartile of cardiorespiratory fitness as reference, odds ratios and 95% confidence intervals for 2nd, 3rd, and 4th quartiles were 1.38 (0.36-5.38), 1.66 (0.35-7.83), and 8.44 (1.80-39.57) (P for trend=0.014).
CONCLUSION: There is a positive relationship between cardiorespiratory fitness and the prevalence of knee osteoarthritis among Japanese men and women. This result suggests that A lot of evidence has suggested that high cardiorespiratory fitness can prevent certain types of internal diseases. However, this study implies that health care professionals should recommend daily physical activity with care regarding osteoarthritis.

THE EFFECTS OF NEUROTRANSMITTERS ACTIVITY AND RECOVERY OF MUSCLE SORENESS BY AURICULAR POINT ACUPRESSURE FOLLOWIN ECCENTRIC EXERCISE

CHIEN, Y.T., LAI, C.C., LIN, H.M., CHANG, J.N.
UNIVERSITY OF TAIPEI

INTRODUCTION:The previous study has shown that long-term auricular point acupressure (APA) treatment could reduce chronic low back pain (Yeh et al., 2015). However, it is not known whether the acute effect on muscle soreness of APA treatment. Thus, this present study investigated whether auricular point acupressure would increase neurotransmitters releasing rates and improve the recovery of muscle damage after maximal eccentric exercise.
METHODS: 16 healthy college students were assigned to two groups randomly, including control group (CON) and auricular point acupressure group (APA). Subjects were performed 100 maximal eccentric contractions (MAX) with knee flexors of non-dominant leg. Muscle soreness, muscle stiffness, joint range of motion, and maximal isometric strength were measured before, immediately after, and 1-4 days after MAX. Norepinephine, epinephine, and dopamine in urine were analyzed before and for 48 hours after MAX. In APA group, subjects were received 4 times auricular compression treatment for 15 minutes in 96 hours after MAX.
RESULTS: Neurotransmitters, such as norepinephrine, adrenaline, dopamine, were showed no significant difference at 48 hours after MAX between two groups ($P > .05$). Nevertheless, muscle functions were both significantly decreased after MAX, but the recovery rate without significant difference between APA and CON group ($P > .05$).
CONCLUSION: These results suggest that auricular point acupressure had no obvious acute-effect on the recovery of lower muscle damage and soreness.

Training and Testing

TRAINING PERFORMANCE TEST OF FEMALE VOLLEYBALL PLAYERS

BIRONE ILICS, K., NAGYVARADI, K., IHASZ, F.
EÖTVÖS LORAND UNIVERSITY PEDAGOGIE AND PSYCHOLOGICAL FACULTY

INTRODUCTION:Ball games require comprehensive ability including physical, technical, mental, and tactical abilities. Among them, physical abilities of players exert marked effects on the skill of the players themselves and the tactics of the team, because ball games demand repeated maximum exertion such as dashing and jumping. Therefore, players must have the physical abilities to make rapid and powerful movements, and aerobic and anaerobic capacities that make them competent in prolonged vigorous offensive and defensive maneuvers.
The aim of the present study is to determine the measured and estimated cardiovascular characteristics with 20 metre Shuttle run and to compare them with pulse variables measured during the training.
METHODS: This study was conducted among female second-class volleyball players (N=13, Age=18,8±2,59). The body height (BH), body weight (BW), relative fat mass (F%), and relative muscle mass (M%) of the players was measured using the InBody 720 Body Composition Analyzer. The trainings were recorded with Sony CX625 handycam and the players wore Polar Team2 chest trap during the exercises. The quality of the players' performance was assessed based on different intensity zones (p50-59%; p60-69%, p70-79%; p80-89%; p90-100%) using VO2max estimation.
RESULTS: The average height of volleyball players is 169.6 ± 5.68 cm and their relative VO2max is 40,96 ± 4.21. Comparing the measured and estimated values of the cardiovascular system, we found that the maximum pulse rate calculated based on the trainings showed a strong correlation with 80-89% of the maximum pulse rate [E1MP-P (80-89%); r=0.955; p<0.001]. The 60-69% pulse rate zone showed an inverse correlation with the 80-89% pulse rate zone [P (80-89% - P (60-69%); r= - 0.905; p<0.005]. The findings suggest that the objectives and the expected quality of the trainings were adequately achieved by 8 players out of the 13, the performance of 2 exceeded expectations, and 3 did not meet the goals.
CONCLUSION: Our study seemed to be effective in achieving our goal. The pulse values at the anaerobic breaking-point, estimated based on a 20 meter Shuttle run, and the training pulse values can contribute to the improvement of the cardiovascular system. Further research is planned on male teams and first-class teams.

CARDIORESPIRATORY AND PERCEPTUAL RESPONSES OF TWO INTERVAL TRAINING AND A CONTINUOUS TRAINING PROTOCOL IN HEALTHY YOUNG MEN

NAVES, J.P., REBELO, A.C.S., SILVA, L.R.B., SILVA, M.S., RAMIREZ-CAMPILLO, R., RAMÍREZ-VÉLEZ, R., GENTIL, P.
FEDERAL UNIVERSITY OF GOIÁS

INTRODUCTION:High Intensity Interval Training (HIIT) can be performed with different effort to rest time-configurations, and this can largely influence training responses. The purpose of the study was to compare the acute physiological responses of two HIIT and one moderate intensity continuous training (MICT) protocol in young men.
METHODS: A randomized cross-over study with 10 men [age, 28.3±5.5years; weight, 77.3±9.3kg; height, 1.8±0.1m; peak oxygen consumption (VO2peak), 44±11mL.kg-1.min-1]. Participants performed a cardiorespiratory test on a treadmill to assess VO2peak, velocity associated with VO2peak (vVO2peak), peak heart rate (HRpeak) and perceived exertion (RPE). Then participants performed three protocols equated by distance: Short HIIT (29 bouts of 30s at vVO2peak, interspersed by 30s of passive recovery, 29min in total), Long HIIT (3

bouts of 4min at 90% of vVO2peak, interspersed by 3min of recovery at 60% of vVO2peak, 21min in total) and MICT (21min at 70% of vVO2peak). The protocols were performed in a randomized order with ≥48 hours between them. VO2, HRpeak and RPE were compared.
RESULTS: VO2peak in Long HIIT was significantly higher than Short HIIT and MICT (43±11 vs 32±8 and 37±8 mL.kg-1.min-1, respectively, P<0.05), as well as peak HR (181±10 vs 168±8 and 167±11, respectively, P<0.05), and RPE (17±4 vs 14±4 and 15±4, respectively, P<0.05), with no difference between Short HIIT and MICT.
CONCLUSION: In conclusion, Long HIIT promoted higher acute increases in VO2, HR and RPE than Short HIIT and MICT, suggesting a higher demand on the cardiorespiratory system. Short HIIT and MICT presented similar physiologic and perceptual responses, despite Short HIIT being performed at higher velocities.

THE EFFECTS OF STATIC STRETCHING OR COMBINED DYNAMIC STRETCHING WITH STATIC STRETCHING ON FLEXIBILITY OF MALE STUDENTS IN SPORTS SCIENCE PROGRAM

BOONSOM, N.

SILPAKORN UNIVERSITY

INTRODUCTION:The development of stretching training programs on flexibility of male students in sports science program, Silpakorn University. This research were purposed to development of stretching training programs on flexibility and compared effect of static stretching and combined dynamic stretching with static stretching on flexibility in during different experimental periods.
METHODS: The subjects were 40 male in first year students of sports science program, faculty of education, Silpakorn University. They were simple random sampled and divided equally in two groups and each group consisted of 10 students. The first group was trained with static stretching program and the second group was trained with combined dynamic stretching with static stretching program. The period of experiment was 3 days per week and total duration 8 weeks. The data of flexibility were collected by using sit and reach test for both groups were taken before experiment, after the 2nd, 4th, 6th and 8th week. The obtained data were analyzed in terms of mean, standard deviations, one-way analysis of variance with repeated measures and multiple comparison by the Bonferroni and t-test Independent were also employed for statistical significant ($p < .05$)
RESULTS: The results of the research were as follow:-
1. The static stretching program had affect on flexibility during different experimental periods significantly at the .05 level.
2. The combined dynamic stretching with static stretching program had affect on flexibility during different experimental periods significantly at the .05 level.
3. The effect between static stretching program (Mean = 16.65, S.D. = 1.56) and combined dynamic stretching with static stretching program (Mean = 20.05, S.D. = 4.40) on flexibility in after the 8th week were significantly at the .05 level
CONCLUSION: The static stretching and combined dynamic stretching with static stretching programs were able to increase flexibility within 8 weeks and combined dynamic stretching with static stretching program was able to increase flexibility better than static stretching program.

EFFECT OF 8 WEEKS GRIP STRENGTH TRAINING ON ADOLESCENT FREESTYLE AND BACKSTROKE SWIMMING PERFORMANCE

PETERSEN, C.1, ALSHDOKHI, K.1, CLARKE, J.1, MASON, T.2

1. UNIVERSITY OF CANTERBURY 2. CANTERBURY SWIMMING

INTRODUCTION:Studies have found positive correlations between isometric hand grip strength and swimming performance (1). Correlations are stronger in shorter compared to longer swimming races and are stronger for freestyle compared to other strokes (2). Maximising propulsive force is a key factor in competitive swimming performance. Yet, it is unknown whether isometric hand grip strength is a proxy for overall strength, which in turn could be related to swimming performance. It is possible that improved handgrip strength itself may relate to swimming performance through improved propulsion. Therefore, our aim was to assess whether improved grip strength results in improved adolescent swim performance.
METHODS: Twenty-six junior club swimmers completed the study and were randomly divided into one of two grip strength training groups or a swimming only control group (n=9, age 12.1 ± 2.3 yrs; 3 males and 6 females). The STRESS group (n= 8, age 11.6 ± 1.6 yrs; 5 males, 3 females) trained with a stress and scrunch ball. Whereas the POWER group (n= 9, age 11.5 ± 1.6; 6 males, 3 females) trained with a power ball and a power gripper device. The training groups completed an 8 week (4 sessions/week, ~5 min/session) progressively increased intensity training programme. Pre and post-training, maximal 50m freestyle and 100m backstroke short-course swimming time-trials were undertaken. In addition, isometric grip strength was measured every two weeks using an adjustable mechanical hand dynamometer (Lafayette Instrument, Lafayette, IN) with the best of 3 attempts taken for each hand.
RESULTS: Statistically, there were no significant between-group changes for any variable. However, over the eight weeks all groups significantly improved their maximal isometric grip strength between 30 - 36% ($p<0.001$): CONTROL (24.5 ± 9.6 to 32.4 ± 10.6 Kg; ES=0.79), STRESS (24.8 ± 7.4 to 32.6 ± 7.4 kg, ES=1.07) POWER (22.8 ± 4.2 to 29.3 ± 3.4 Kg; ES=1.70). All groups had only a trivial magnitude of change (ES= 0.02 - 0.04) in 100m backstroke performance. Whereas, for 50m freestyle performance only STRESS (42.04 ± 6.92 to 40.49 ± 5.95 s; ES=0.24) and POWER groups (43.97 ± 8.74 to 41.93 ± 6.99 s; ES=0.26) had statistically significant ($P<0.05$) yet small magnitudes of improvement (3.4 to 4.1%). In comparison, the CONTROL group (41.99 ± 9.17 to 40.58 ± 7.29 s, ES=0.17) displayed a non-significant ($P=0.09$) change in 50m freestyle performance.
CONCLUSION: Despite all groups improving isometric grip strength by at least 30%, 100m backstroke performance did not improve. The eight weeks of grip strength training may result in a small improvement in 50m freestyle performance. Yet, we suggest other factors (overall strength, technique changes) be investigated as more critical performance influencers.

THE INVESTIGATION INTO THE DIFFERENCE IN WORKLOAD CAPACITY BETWEEN ELITE SOCCER PLAYERS AND NON-PLAYER CONTROLS

CHENG, Y.C.1, LIN, C.C.1, LIANG, C.W.2, HUANG, H.W.1, YANG, C.T.3, WANG, C.H.1

NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION:Previous studies have shown that there is a profound perceptual-cognitive expertise in elite athlete. However, most of researchers made such conclusions only by means of evaluating error rates and mean reaction times (RTs), which cannot be used to infer the information processing efficiency in athletes. It thus remains to be determined whether this leads to dismissal of crucial information regarding the effects of interest. Here we adopted a non-parametric approach (systems factorial technology, SFT) combined with functional principal component analysis (fPCA) to further understand the information processing property in elite athletes.
METHODS: Thirty male Division I collegiate motor experts (aged 20.10 ± 0.92 years, with professional experience in soccer training of 11.31 ± 2.09 years) and 30 male non-player novices from general student population (aged 21.73 ± 1.43 years) participated in the experiment. This study adopted a redundant-target detection, in which participants had to monitor two sources of visual features (i.e., color and shape) and make a positive response based on the detection of either one or both sources of information, to evaluate individuals' perceptual capacity.
RESULTS: Although the evidence for the group difference in processing speed was extremely weak (BFInclusion = 0.55), the analysis of SFT revealed marginal evidence for a difference in the number of individuals classified as super-capacity or non-super capacity in each group (BF10 = 1.712). Moreover, the outcome of fPCA identified a crucial component accounting for 42% of the variance in processing capacity across all participants and showed higher scores in the soccer players relative to the controls (BF10 = 4.887).
CONCLUSION: Collectively, our findings suggest that elite soccer players and non-player controls may process the redundant information in a different manner. To elaborate, elite soccer players may tend to adopt a global and flexible processing strategy to deal with the multiple visual features, which may be a potential mechanism supporting perceptual-cognitive expertise in elite soccer players.

THE FORGOTTEN AEROBIC CAPACITY MARKER IN HEALTHY OLDER ADULTS

MARTÍNEZ LABARI, C., GARCIA-TABAR, I., GOROSTIAGA, E.M.

STUDIES, RESEARCH AND SPORTS MEDICINE CENTRE, GOVERNMENT OF NAVARRE, SPAIN; BIKOA SL, SPAIN; DEPARTMENT OF PHYSICAL EDUCATION AND SPORT, FACULTY OF EDUCATION AND SPORT, UNIVERSITY OF THE BASQUE COU

INTRODUCTION:The aim of this study was to demonstrate that the Lactate Threshold (LT), conceptually comprehended as in the old days (Owles, 1930), could be more accurate and functional method in comparison with the most common functional submaximal exercise field tests used for aerobic conditioning assessment and aerobic (either continuous or intermittent) exercise training guidance purposes.
METHODS: Twelve 61 to 77 yrs old male were recruited from a Physical Activity Program for persons over 55. Participants first underwent a cardiopulmonary treadmill exercise (CPX) test to determine maximal oxygen uptake (VO2max). During the remaining sessions, participants performed 3 field walking tests (FWTs) in a randomized counterbalanced order. Field walking tests were 1) the 6-minute field walking test (6-Min-FWT) (Lipkin et al., 1986), 2) the incremental continuous shuttle field walking test (CS-FWT) (Singh et al., 1992), and 3) a discontinuous version of the shuttle field walking test (DS-FWT) enabling LT determination.
RESULTS: The DS-FWT (LT test) ended at 6.2 ± 0.8 km•h-1 corresponding to 71 ± 8% of maximal heart rate (HRmax) with a blood lactate concentration of 1.6 ± 0.6 mmol•L-1 which was similar (P > 0.05) to that presented before the test. The 6-Min-FWT (6.8 ± 0.7 km•h-1; 92 ± 9% HRmax, 4.3 ± 1.3 mmol•L-1) and the CS-FWT (6.8 ± 0.8 km•h-1; 89 ± 2% HRmax, 4.3 ± 1.7 mmol•L-1) finalized at a higher exercise intensities (P < 0.001), indicating the higher physical effort required in comparison with LT testing. Furthermore, LT was the best VO2max predictor with a Pearson correlation magnitude of r = 0.91 (P < 0.001; SEE = 3.0).
CONCLUSION: Due to the methodological-based errors of the gas analyzers (Garcia-Tabar et al., 2015) and the inaccuracy of VO2max to individualized training exercise intensity (Wolpern et al., 2015), the LT should have a greater consideration to predict VO2max and assess aerobic capacity in Physical Activity Program for persons over 55.

THE EFFECTS OF TWO DIFFERENT DYNAMIC STRETCH VELOCITIES ON JOINT FLEXIBILITY AND MUSCLE STRENGTH

MIZUNO, T.

NAGOYA UNIVERSITY

INTRODUCTION:It has recently been recommended that dynamic stretching (DS) should be included in warm-up routines before exercise (1). However, the optimal DS protocol for subsequent exercise performance has not been established. A previous study showed that fast DS was associated with subsequent greater jump height than slow DS (2). Here, we aimed to determine the effects of two different DS speeds on joint range of motion (ROM), passive resistive torque, and isometric muscle strength.
METHODS: Fifteen healthy male subjects (mean age 20.5 ± 1.1 years) performed DS at two different speeds: at maximal active ankle plantarflexion-dorsiflexion speed (DS100), and at 50% of maximal active speed (DS50). A passive dorsiflexion test and isometric maximal voluntary contractions (MVC) of the ankle plantar flexors and dorsiflexors at an ankle joint angle of 90° were performed before and after DS. During the passive dorsiflexion test, ankle ROM and passive resistive torque were measured when the ankle was passively dorsiflexed at 1°/s to its maximal ROM. The DS consisted of four sets of 10 ankle plantarflexions/dorsiflexions. Subjects were instructed to repeat the ankle joint movements between maximal plantarflexion and maximal dorsiflexion. For DS100, participants flexed and extended their ankle as quickly as possible, whereas for DS50 the rhythm of the DS was dictated by a metronome. Subjective fatigue during DS was assessed using a visual analogue scale.
RESULTS: Maximal ankle dorsiflexion ROM was significantly higher after both DS100 and DS50 (P<0.05), but there was no significant difference between these groups. Passive resistive torque at maximal dorsiflexion angle was higher after both DS regimens (P<0.05), whereas the passive resistive torque at submaximal dorsiflexion angles was similar. The isometric MVC of the ankle plantar flexors and

dorsiflexors were also similar after both regimens. However, there was a larger degree of subjective fatigue after DS100 than DS50 (P<0.05).
CONCLUSION: Dynamic stretching speed does not influence subsequent joint flexibility and isometric MVC. However, DS of moderate speed is recommended, because faster DS appears to be associated with greater fatigue.

EFFECT OF PRIOR KNOWLEDGE OF INCREASE IN RUNNING SPEED ON THE CARDIORESPIRATORY SYSTEM DURING RUNNING

MIGITA, T.

KURUME UNIVERSITY

INTRODUCTION:During long-distance races, a sudden increase in running speed could cause delayed physiological responses because the acceleration would induce a sudden energy requirement. As a result, physiological responses to change in running speed could determine race performance. This study investigated whether prior knowledge of increase in running speed among runners affected cardiorespiratory responses during running.
METHODS: Eight healthy male volunteers (age, 20±1 years; height, 167±3 cm; weight, 63.2±8.3 kg; values presented as mean±SD) participated in this study. At the beginning, they performed a velocity-incremental maximal test. Based on the results of the maximal test, running velocities corresponding to ventilation threshold (VT) and maximal oxygen uptake (VO2peak) were calculated. Second, subjects carried out two types of 10-min transient submaximal running tests: one in which they had prior knowledge of the increase in running speed during running (aware) and one in which they did not (unaware). The 10-min transient running test consisted of 4 minutes of pre-increase and 6 minutes of post-increase continuous running. Running velocity during pre-increase continuous running corresponded with the velocity at VT while running velocity during post-increase continuous running corresponded with the velocity of Delta 40% (VT + (VO2peak – VT) x 0.4). Pulmonary gas exchange parameters and heart rates were measured during all exercise tests. Oxygen uptake (VO2) parameter was analyzed using non-linear regression analysis. A mono-exponential model was used for pre-increase and a double-exponential model was used for post-increase.
RESULTS: The mean VO2peak was 3318±448 ml/min. The VO2 at VT and Delta 40% was 2099±259 ml/min and 2586±303 ml/min, respectively, which corresponded to 63.6±5.6 % and 78.1±3.3 % of the VO2peak, respectively. The running velocities at VT and Delta 40% were 117.9±25.5 m/min and 167.0±20.3 m/min, respectively. During post-increase running, the time constant for VO2 kinetics was 58.1±16.0 sec (aware) and 44.5±16.6 sec (unaware), showing no significant difference between running tests which had prior knowledge of the increase in running speed and those which did not. The remaining cardiorespiratory parameters in this study, which concluded heart rate, respiratory rate and respiratory exchange ratio, showed no different responses between two types running.
CONCLUSION: In conclusion, prior knowledge of increase in running speed did not affect cardiorespiratory system during running, at least not with respect to the change in running speed within the confines in this study,

EFFECTS OF DIFFERENT TEMPOS IN JUMPING EXERCISES ON LOWER EXTREMITY MUSCLE STRENGTH AND FUNCTION OF OLDER ADULTS

NAKATANI, T.1,2, KINO, K.2, YAMAMOTO, H.2, MATSUMOTO, Y.2, TERADA, K.1,2, SHIRAISHI, A.1,2, NADAMOTO, M.3

1: TENRI UNIVERSITY , 2: TENRI UNIVERSITY GRADUATE SCHOOL , 3: ST. ANDREW'S UNIVERSITY OF EDUCATION

INTRODUCTION:Decline of muscle strength and function are associated with impairment of normal daily activities (Milanovic et al., 2013). Particularly, extensors of the knee joint's muscular group largely decline, making it difficult to rise from the floor and chairs and to climb stairs (Marko et al., 2012). Such muscle weakness increases elderly people's risk of falling. Therefore, strength and power training are needed. Therefore, this study investigated effects of a jumping exercise's differing tempos on older adults' lower extremity muscle strength and function.
METHODS: A total of 26 community-living men and women aged 63–78 years participated in this study. Participants were randomly assigned to either a quick 108 tempo (QJ, n = 14) or a slow 60 tempo per minute (SJ, n = 12) jumping exercise group. Both groups performed one set of jumps until they reached a level of exertion they perceived as difficult (Borg-RPE Scale of 15). Both groups trained three times a week for 12 weeks and participated in 60-min supervised group exercise sessions held once every two weeks at a local health centre. Outcome measures included the right and left lateral walk (RLW and LLW), the four-square step (4SS), foot stepping (FS), two-step stride length (2SL), vertical ground reaction force per body weight (SUI) and rate of force development (RFD) in sit-to-stand movement.
RESULTS: At baseline, groups had no differences in age, height and weight ($p > 0.05$). Repeated measures analysis of variance showed the interaction's significant effect between exercise and time on 2SL ($F = 6.23$, $p = 0.002$) and a significant main effect of time of measurement on LLW ($F = 12.21$, $p = 0.002$) and 4SS ($F = 7.18$, $p = 0.013$). The SJ group's 2SL (210.8 ± 21.1 to 227.3 ± 27.2, $p = 0.009$) significantly improved after the 12-week training, but the QJ group's did not. No significant difference was shown between the jumping exercise tempo in RLW, FS, SUI and RFD.
CONCLUSION: For improving muscular strength related to stride length in older adults, performing the jumping exercise at a slightly slower tempo was more effective than at the quick tempo. The jumping exercise is simple and safe—a very practical method for improving lower extremity muscle strength and function.

ON THE CHANGES IN BRAIN WAVES AND COGNITIVE FUNCTIONS CAUSED BY THE LOW AND HIGH-INTENSITY TRANSIENT EXERCISE

NAKAJIMA, S.

KYORITSU WOMENS JUNIOR COLLEGE

INTRODUCTION:In recent years, an accumulation of stress and chronic fatigue have been identified as a problem. They can cause physical and mental disorders and the conditions may become severe. This is a serious problem not only for workers but also for college students, and there have been reports that students who have problems coping with stress are on the increase. On the other hand,

exercise is thought to be effective not only for the prevention of diseases such as lifestyle-related diseases and the relief of the symptoms but also for the elimination of stress and the alleviation of fatigue. In fact, there have been many reports on the effectiveness of exercise in terms of reducing stress, anxieties, and depression and improving memories and learning. Some of these reports claim that daily exercise also brings various functional changes in the brain. Moreover, there has been a report in the research which targeted college students that those with exercise habits are better at coping stress and their mental states stay stable.
This study aimed to examine the changes in brain waves in order to find out whether transient exercise is effective for reducing stress. At the same time, I also conducted the Stroop color-word test to examine the changes in cognitive functions and measured them using salivary amylase concentration which is a non-invasive biomarker as an index for the evaluation of the stress level of the sympathetic nervous system.
METHODS: I had a group of healthy female college students as the subject of the trial where each of them were put in the following three states: (1) resting (2) running on a treadmill for 30 minutes using about 40% of stamina (3) running on a treadmill for 30 minutes using about 70% of stamina. I took their EEGs before and after the exercise using a simple electroencephalograph, Brain Pro FM - 929 (FUTEK). In regard to the brainwaves, I set the frequencies of the α-wave and the β-wave to be 7～13Hz and 17～26Hz respectively and used the values calculated by the analysis software, Pullax F, for the distribution ratio of both of the waves. I used the scored values for the Stroop color-word test and used a salivary amylase activity monitor (NIPRO) to measure the concentration of the salivary amylase.
RESULTS: In regard to the concentration of the salivary amylase before and after an exercise, it increased by 97.5% after the exercise using about 40% of stamina compared to that before it, and it increased by 167.2% after the exercise using about 70% of stamina compared to that before it. Meanwhile, the α-wave increased by 9.4% after the exercise using about 40% of stamina and by 16. 8% after the exercise using about 70% of stamina.
CONCLUSION: .

EFFECTS OF PLYOMETRIC TRAINING INTRODUCED IN MIDDLE SCHOOL PHYSICAL EDUCATION CLASSES

TERADA, K.1,2, MIYAKE, Y.2, KAWAKAMI, T.2, HIRAMOTO, K.2, KANEYASU, A.2, MATSUMOTO, Y.2, KAWAKAMI, K.1, NAKATANI, T.1,2, MIYAI, N.3, ARITA, M.3, UTSUMI, M.3

1: TENRI UNIVERSITY, 2: TENRI UNIVERSITY GRADUATE SCHOOL, 3: WAKAYAMA MEDICAL UNIVERSITY

INTRODUCTION:From the belief that it is critical to improve so-called Stretch-Shortening Cycle (SSC) (Bosco, 1983) movement performance related to instantaneous force and agility starting from the middle school years (Ramirez, 2018), we proposed in this study to implement Plyometric Training (PMTr), which improves SSC movement performance, for short durations on a regular basis within physical education classes in conditions under which all students could participate, and under the guidance of specialists. Specifically, the purpose of this study was to attempt intervention with PMTr for general middle school students as subjects for a set period of time, using one portion of school physical education class time, and to shed light on its effects.
METHODS: The subjects were 88 male and 87 female middle school students. We randomly assigned two classes in each school grade for the entire class to be either the PMTr group (Tr group, n=89) or the control group (C group, n=86). The Tr group practiced PMTr using single-leg rebound jumps (RJ) and split squat jumps (SSJ) as part of their warm up exercises at the beginning of physical education classes, using about five minutes, at a frequency of three times per week, over a period of eight weeks. In order to investigate the effect of PMTr, we conducted tests assessing instantaneous force and agility before and after the intervention period.
RESULTS: When we performed iteration retrospective two-way analysis of variance, in boys interaction with rebound jump index (RJ-i) and vertical jumping were observed. In girls interaction with vertical jumping was observed. Effects of the intervention were observed in the Tr group. In the analysis by gender and school grade, differences in the items showing change were observed, but these suggested the existence of effects related to age and growth. Also, we observed a relative weight increase in the C group. No adverse events were observed during the intervention period.
CONCLUSION: We think that intervention with middle school students using PMTr for a set period had the effect of increasing SSC movement performance, since RJ-i improved, particularly in males. Furthermore, the results suggest the possibility that the PMTr in this study has an inhibitory effect on weight gain (Racil, 2015).

MARATHON TIME PREDICTION USING THE 1KM RUN

ADACHI, T.1, ADACHI, H.2, NAKASHIMA, N.3

1 :OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES, 2: RITSUMEIKAN UNIVERSITY, 3: MIZUNO SPORTS SERVICE

INTRODUCTION:For a runner, the distance of 1km is used as a measure in various kinds of training and races, including timed runs, distance running and interval running. The speed with which a recreational runner can run a distance of 1km is one criterion for the runner to gauge his running ability and can be assumed to be the absolute speed.
The aim of this study is to identify the relationship between the time taken to run 1km and marathon time targeting recreational runners and, to thereby, examine marathon time prediction.
METHODS: The subjects were 25 male and female marathon runners aged between 31 and 65 years belonging to a marathon club with a marathon time of 3 hours 33 seconds to 6 hours 35 minutes and 19 seconds.
The 1km run time trial was not conducted for the purpose of experimentation but was part of the regular training conducted by running clubs and the best record from the several times that it was conducted was used. The 1km run time trial was implemented using a circuit of 600 m to 700 m and a one-way 500 m round trip running route.
RESULTS: The morphological characteristics of the subjects were height 162.5 ± 8.5cm, weight 54.9 ± 9.2 kg and a BMI of 20.7 ± 1.9. The result of the 1km run time trial was in the range of 3 minutes 26 seconds to 5 minutes 45 seconds with an average of 4 minutes 30 sec-

onds ± 30 seconds. The amount of training was from 8 to 80 km per week with significant differences between individuals and with the average being 33.3 ± 14.7km.
The average speed was calculated from the 1km run time and the marathon time and an average of 72.7 ± 6.2%V0 obtained by calculating what percentage of the 1km run speed（V0）the marathon corresponded to. As differences among individuals were seen in the %V0, we compared the relationship between marathon time and %V0. The faster the runner, the higher the %V0; runners with a marathon time of 3 hours had a 80%V0, those with a marathon time of 4 hours had a 75%V0 and those with a marathon time of 5 hours had a 66%V0, indicating that a marathon time difference of 1 hour showed a drop of 5%V0.
When comparing the relationship between marathon time and the 1km run time, a positive linear relationship of $y = 1.125x - 40.656$ was recognized in both. The correlation coefficient was $r = 0.822$ and the coefficient of determination was 67.6%, revealing that marathon time could be explained at a contribution rate of about 70% by the 1km run time.
CONCLUSION: This suggests that marathon time could be predicted with a high rate using only 1km run time. Further, data useful for training and for setting the pace in a race was also obtained. However, the target of this study were general recreational runners aged 30 and above, restricted to a competition level range of 3 hours to 6 and a half hours of marathon time. Therefore, at this stage, the findings of this study would not apply to runners at a high level of competition, such as student athletes, corporate sports teams and professional runners.

ASSOCIATION OF LOWER LIMB MUSCLE ACTIVITIES WITH INCREASED METABOLIC RATE DURING UPHILL SLOPE RUNNING AT A CONSTANT HIGH GRADIENT

HIRAKOBA, K., TOKUI, M.

KYUSHU INSTITUTE OF TECHNOLOGY AND KYUSHU KYORITSU UNIVERSITY

INTRODUCTION:In view of a research field related to uphill slope running (USR), it can be imagined easily that muscle activity in the lower limb muscle group is associated with an increase of metabolic rate at a higher gradient during USR. This study, therefore, was carried out to reevaluate a relationship between lower limb muscle activities on the selected seven sites and increase in metabolic rate at a higher gradient during USR, compared to a level running (LR).
METHODS: Ten healthy middle-aged recreational runners (60±6.3 years) were used as the subjects. On the first visit to the laboratory, the subjects performed a uphill slope incremental running test on a treadmill as a preliminary trial, which composed of 3 min-rest and increasing 2% per 2 min from 0% to 10% or 12% of gradient at an individually chosen comfortable velocity, to obtain a relationship between oxygen uptake (VO2) and gradient, and a peak value of VO2 (VO2peak). Three gradients in main exercise test (MET) were calculated from the relationship between VO2 and gradient. Thus VO2 at LR was adopted as Δ0% (0% gradient), and another two gradients (Δ30% and Δ60%) were set by VO2 at LR plus 30 % or 60 % of a difference of VO2 between LR and VO2peak, respectively. On the 2nd and 3rd visit, MET, consisting of 3 min-rest and three levels of gradients corresponded to Δ0%, Δ30% and Δ60% for 6 min, were carried out in a random order. VO2 and electromyogram (EMG) signals on seven sites from lower limb muscle group were measured continuously throughout MET.
RESULTS: VO2 in Δ0% and Δ30% were almost remained throughout running exercise after reaching a steady state level, while VO2 in Δ60% was progressively increased from 2nd min of the onset of exercise until the end of exercise. As a result, VO2 (2412±319 ml·min-1) at exercise end point of Δ60% revealed to be significantly higher ($P<0.01$) compared to Δ0% (1869±342 ml·min-1). Sum of integrated EMG on seven sites (iEMGsum) showed to be significantly higher at exercise end point of Δ60% (10.90±1.59 mV*s) compared to Δ0% (8.96±1.35 mV*s). In relative changes at exercise end point in Δ30% and Δ60% based on Δ0%, there was a significant relationship between VO2 and iEMGsum ($r= 0.764$, $P<0.01$). When comparing iEMG values at exercise end point in Δ60% with those in Δ0%, the relative changes in major gluteus (74.5%↑), rectus femoris (39.3%↑) and biceps femoris (50.0%↑) were larger rather than another muscle activities measured.
CONCLUSION: It has been indicated that the reduction of elastic energy accompanying with the rise of gradient during USR increases the activity of the lower limb muscle group. The present results show that USR at a higher gradient would lead to the enhancement in muscle activities of especially above-mentioned three lower limb muscles. Consequently, it is inferred that muscle activities of the listed three exercising muscles at a higher gradient plays an important role for the increase in metabolic rate during USR compared to LR.

RELATIONSHIPS BETWEEN RATE OF DECLINE IN SPEED IN SPRINT AND FORWARD HEAD POSTURE IN 9-12 YEARS OLD CHILDREN.

SUZUKI, K.1, HAYASHI, R.2

1: CHUBU GAKUIN UNIVERSITY, 2: GIFU UNIVERSITY

INTRODUCTION:Good posture is often emphasized by coaches when they instruct sprint running1) 2) 3). Actually, when monitoring children's sprint form, bad posture looks having adverse effect on sprint performance. But Thompson, A et al. 3) says "little or no research has investigated about optimal posture characteristic within sprint". Therefore, we investigated relationships between static posture and rate of decline in speed (RDS) which is important factor for assessment of sprint performance.
METHODS: Participants were 9 to 12 years old 182 children (97 boys and 85 girls). The sideways static posture was recorded by camera and 50m sprint running was clocked and recorded. About posture assessment, we used a method by Uota, S et al. 4) as a reference, then forward head angle (FHA) was calculated as an index of bad posture by positions of lateral malleolus, middle point of the upper side of pelvis, protuberance of thoracic kyphosis, and external acoustic foramen. And about 50m sprint running, RDS and standardized time by age and sex were calculated. Participants were classified into 3×3 groups by standardized time (TIME; FAST, AVERAGE, SLOW) and the level of FHA (POSTURE; GOOD, NORMAL, BAD), then difference of RDS by groups were compared.
RESULTS: Two-way ANOVA on RDS with standardized time and the level of FHA as factors detected no interaction between TIME and POSTURE ($F2, 179=2.31$, n.s.) and revealed an effect of TIME ($F2, 179=16.75$, $p < 0.01$) and POSTURE ($F2, 179=4.59$, $p < 0.05$). RDS was higher in sequence of SLOW > AVERAGE > FAST within TIME and higher in BAD than NORMAL within POSTURE. Additionally, the results of one-way ANOVA on RDS in each TIME groups with POSTURE as factor revealed an effect in SLOW ($F2, 52=4.85$, $p < 0.05$) which was higher in BAD than NORMAL. And no significant difference was detected in FAST ($F2, 60=0.73$, n.s.) and AVERAGE ($F2, 61=0.12$, n.s.).
CONCLUSION: From these results, some possibilities about relationships between sprint performance and posture were suggested as below. (1) Bad posture could be a factor which makes children's speed of sprint running decrease on last phase in 50m. (2) Especially about relatively slow children in age or sex groups, bad posture could be critical factor which limits sprint performance.

TEST-RETEST RELIABILITY OF ISOKINETIC KNEE TESTING USING THE NOVEL ISOKINETIC SMM IMOMENT DYNAMOMETER

KAMBIC, T., LAINŠCAK, M., HADŽIC, V.

GENERAL HOSPITAL MURSKA SOBOTA; FACULTY OF SPORT, UNIVERSITY OF LJUBLJANA; FACULTY OF MEDICINE, UNIVERSITY OF LJUBLJANA

INTRODUCTION:Isokinetic dynamometry is a gold standard for testing maximal strength both in elite sport and rehabilitation settings (1). To be recommended as a tool in clinical practice, such tests should be valid and reliable. Although relative reliability parameters of knee dynamometry (e.g. intraclass correlation coefficient) are commonly reported, there is still a paucity of research regarding the absolute reliability parameters (2). The aim of this study was to assess both the absolute and relative reliability of isokinetic knee flexion and extension using the novel SMM iMoment dynamometer.
METHODS: A total of 19 participants [13 males and 6 females, aged 24.2 (2.4), height 177.5 (9.0) and weight 75.71 (70.70)] performed two identical knee isokinetic tests on the SMM iMoment dynamometer with 7.88 (2.45) days of rest between measurements. Peak torque of knee extension and flexion were determined at 60°/s over the 60° range of motion (90° - 30°). Absolute and relative reliability was assessed using standard error of measurement (SEM and SEM %), smallest real difference (SRD), and intraclass correlation coefficient (ICC), respectively.
RESULTS: Moderate [0.892, (95% CI: 0.718, 0.958), p<0.001] to excellent [0.988, (95% CI: 0.967, 0.995), p<0.001] relative reliability using ICC was obtained for peak knee torque. Absolute reliability assessed with SEM % [1.7% - 2.7%] was very low. Similarly, the SRD % was very low, with range from 4.0 % to 7.8 %. Furthermore, there were no significant correlation, neither Bland-Altman plots showed no signs of heteroscedasticity.
CONCLUSION: Our measurement protocol has presented excellent reliability of the novel SMM iMoment isokinetic dynamometer. Based on our findings we suggest that this dynamometer can be used in clinical settings to measure maximal knee strength.

PERFORMANCE AND PROGRESSION OF NEW ZEALAND'S ADOLESCENT BACKSTROKE SWIMMERS.

ALSHDOKHI, K., PETERSEN, C., CLARKE, J.

UNIVERSITY OF CANTERBURY

INTRODUCTION:Swimmers are very interested in relative performance times against age-matched peers but this performance is difficult to track as performances fluctuate over time from competition-to-competition. Varying maturation effects between swimmers also increases this prediction difficulty. Coaches often use an estimated rate of improvement to predict swimmers future performance with these predictions usually based on the coaches personal experiences from a relatively small number of swimmers. Therefore our aim is to provide coaches with the historical age-based data of yearly performance progression giving coaches a greater understanding of the likely range for an individual swimmer's rate of improvement.
METHODS: Data was extracted from Swimming New Zealand's national online database from 2006 - 2017 (9956 swimming years) and analysed to determine both mean performance time and mean yearly percentage improvement by age (8 to 18 years), gender, and pool length (25m = Short course; 50m = Long Course) for the 50, 100 and 200m backstroke events. For each swimmer, a percentage difference from the swimmer's best time (PB) for the current year was calculated by comparing to their best time from the previous year. In a swimmer's first year of swimming, the swimmer's first swim was used as the comparison baseline. Any starting year where the swimmer only had a single swim was excluded from the analysis.
RESULTS: As expected there was a diminishing rate of improvement as swimmers matured, with a trend for the largest yearly improvement in backstroke occurring between ages 8 to 13 years. The highest percentage yearly improvement was for female 8 year old swimmers in the 50m short course event (9.6 ± 6.7 %), while males had their greatest improvement at age 10 years, again in the 50m short course event (9.3 ± 5.5 %). Across all distances, swimmers of both genders progressed faster the shorter the distance and this was consistent across both short and long course events.
CONCLUSION: Referring to our data of mean (± SD) backstroke times, standardised Z-scores can be determined to show how an individual swimmer compares to their population, and what a certain percentile time would be. For example, an 8 year old swimmer with a PB time of 54s for the 50m short course event would be calculated to be 0.35 SD slower than the mean time (50.98 s) of 8 year old swimmers; while the 90th percentile 50m short course time for this group would be calculated to at 43.66 s.
Accessing data from a large number of swimmers over multiple years provides the mean (± SD) population data necessary for the calculation of a swimmers standardised Z-score in relation to their age-matched peers and allows for greater precision in predicting likely rates of improvement. In summary, these data can be used to objectively evaluate progress, and assess the success of any longitudinal training intervention.

STUDY OF PEAK TORQUE, TOTAL WORK, H/Q AND R/L RATIO IN MODERN PENTATHLON ATHLETES

YOON, J.R.

KOREA NATIONAL SPORT UNIVERSITY

INTRODUCTION:The purpose of this study is to diagnose and evaluate the isokinetic strength factors of the knee joint, which are important determinants for athletic performance, based on isokinetic strength tests performed for national-level modern pentathlon athletes. Also this study aims to provide important data that can be used to develop professional fitness training program for KNSU modern pentathlon athletes.

METHODS: Modern pentathlon athletes(n=15) who fully understood the objectives of the research and also actively expressed their intention to participate were selected as subjects. The average of their physical characteristics were as follows: age=19.87yrs, height=178.81cm, weight=71.34kg, %body fat=11.36, BMI=22.29, and skeletal muscle mass=36.10kg. Isokinetic muscle function tests were performed by measuring flexion and extention of the knee joint using Humac Norm(USA). For isokinetic strength of the knee joint, flexors and extensors were measured 5 times at a speed of 60°/sec. As an adaptation process, 2 times of preliminary measurements were taken. Also, 1 minute of break time was taken between each measurement to minimize the influence from the previous test. Measurment parameters were peak torque & total work/body weight, H/Q ratio, R/L extensors and R/L flexors for isokinetic strength of right/left knee joint. To analyze the collected data regarding isokinetic strength, basic descriptive statistics technique by Window SPSS 17.0 was used.
RESULTS: The isokinetic strength tests of national-level modern pentathletes showed that the peak torque were 303.39%BW and 303.22%BW in the right and left extensors respectively, and total work were 1541.39%BW and 1550.76%BW in right and left extensors respectively. The peak torque were 161.98%BW and 164.74%BW in right and left flexors respectively, and the total work was 919.31%BW and 945.87%BW in right and left flexors respectively. Flexors/Extensors(H/Q: unilateral) of right and left knee joints were 53.47% and 54.47% respectively. The peak torque and the total work of right and left strength(bilateral) in the extensors were 4.60% and 6.80%, respectively. And the peak torque and the total work of right and left strength in the flexors were 7.67% and 7.07%, respectively.
CONCLUSION: The average of H/Q ratio was appeared to be less than 60%, which is the standard criterions for a well-balanced athletes, the R/L ratio of extensors and R/L ratio flexors was less than 10%, meaning the isokinetic strength of left and right knees joints are well-balanced. Therefore, it suggest that these athletes are focus on the following: (1) maintaining at least within the current level of the R/L ratio of extensors, R/L ratio of flexors, and (2) improving the H/Q ratio by performing weight tranining exercises to enhance the hamstrings muscle strength.

IMPACT OF PRECAUTIONS COMPLIANCE ON BODY COMPOSITION MEASUREMENT BY SEGMENTAL BIOELECTRICAL IMPEDANCE ANALYSIS

CHAEEUN, C.

INCHEON NATIONAL UNIVERSITY

INTRODUCTION:Body composition is strongly associated with the risk of several chronic diseases. Bioelectrical impedance analysis (BIA) is a relatively simple, quick and non-invasive technique, to measure body composition. In this study, we assessed whether the major precautions such as urination, water intake, exercise and meal intake had significant effect on BIA and body composition.
METHODS: To achieve the purpose of the study, research was conducted on 32 healthy male (n=18, 23.28±0.65) and female (n=14, 21.79±0.69) adults. Segmental BIA was measured using Inbody720(Biospace, Korea). Body composition was measured by observing all the precautions except for 4 conditions of urination, water ingestion, exercise and meal each visit in the laboratory. In the case of urination, pre- and post- were measured. Water ingestion, aerobic exercise, and meal intake were measured immediately after treatment, after 30 minutes, 60 minutes, and 120 minutes.
RESULTS: Body weight(p=<0.0001), skeletal muscle mass(p=<0.01)and basal metabolic rate(BMR)(p=0.003) were significantly decreased after urination. Water ingestion significantly increased body weight (p=<0.0001), body fat mass (p=0.0001) and percentage of body fat (p=<0.0001). Acute 30 minute aerobic exercise significantly decreased body weight(p=<0.0001), body fat mass(p=0.0001), percentage of body fat(p=0.0038), whereas exercise increased skeletal muscle mass(p=0.0128) and BMR(p=0.0068). Impedance was significantly decreased immediately after exercise(p=0.0038), but it was significantly increased after 120 minutes(p=0.0336). In addition, body weight(p=<0.0001), skeletal muscle(p=0.0237) and BMR (p=0.0273) were significantly increased after meal intake.
CONCLUSION: The present study suggests that precautions such as urination, water ingestion, exercise, and meal should be observed to determine accurate body composition.

A ONE-WEEK EUROPEAN ALPINE TREK ENHANCES AEROBIC FITNESS BUT NOT LEG POWER OR LEG STRENGTH.

RAMSBOTTOM, R., VARNHAM, R., BARDIN, J., TURNER, K.

OXFORD BROOKES UNIVERSITY

INTRODUCTION:Walking is the most common form of human locomotion and trekking, particularly long distance treks, has become more popular. Previous studies have mainly investigated the effect of trekking on energy expenditure (1). There are few reports of how trekking may influence aerobic fitness or leg strength. Therefore the aim of the present study was to investigate the effect of a one-week alpine trek on aerobic fitness and leg strength.
METHODS: Between 2009 and 2016 one hundred and ninety-three students from Oxford Brookes University (n=109 men; age, 20.9 ± 2.0 years, height, 1.81 ± 0.06 m, 79.6 ± 10.8 kg and n=84 women; age, 20.9 ± 2.0 years, height, 1.67 ± 0.06 m, 62.5 ± 10.7 kg) participated in Le Tour du Mont Blanc (approximately 160km) over a seven day period. Aerobic fitness was assessed during an incremental treadmill test to volitional exhaustion with O2 uptake and CO2 production monitored breath-by-breath. Jump height from a standard start position was measured using a Vertical Jump Mat and dynamic leg strength was assessed using a Concept2 Dyno. Differences between men and women were assessed using 2-way ANOVA (SPSS, ver. 24).
RESULTS: There was a significant increase in aerobic fitness for both men (n=94, 52.2 ± 6.4 vs. 53.9 ± 5.9 ml kg-1 min-1) and women (n=67, 43.2 ± 5.3 vs. 44.3 ± 5.9 ml kg-1 min-1) (P<0.01). There was no change in jump height for men (0.41 ± 0.07 vs. 0.40 ± 0.08 m) or women (0.28 ± 0.05 vs. 0.28 ± 0.06 m). Similarly there was no change in dynamic leg strength (1753 ± 420 vs. 1714 ± 433 N) (men; n=102) and (1237 ± 255 vs. 1251 ± 271 N) (women; n=79). There was no sex difference in the responses to the trek.
CONCLUSION: A one-week alpine trek improved aerobic fitness in men and women with no corresponding change in leg power or measures of dynamic leg strength.

THE 2018 MARATHON WORLD RECORD SHOWS THE POSITIVE ASYMMETRY PACING STRATEGY EFFECTIVENESS

PALACIN, F., PYCKE, J.R., CARBILLET, T., BILLAT, V.

UNIVERSITÉ EVRY VAL DESSONNE

INTRODUCTION:Recently, Kenyan Eliud Kipchoge lowered the marathon world record by more than one minute in Berlin. The Olympic champion already made an impression 6 months earlier while trying to complete the first unofficial sub two-hour marathon in Monza.

The difference between the two marathons is that in Monza, the instructions were to run at a constant pace whereas in Berlin the speed was significantly variable. The purpose of this study is to analyze the running pattern to achieve this new best performance beyond the well-known negative split with a more accurate analysis of the speed time series. More precisely, instead of trying to keep a constant pace until fatigue like mass runners would do, Eliud Kipchoge ran in what we named a positive asymmetric(1) way.
METHODS: To achieve this study, we examined the time per kilometer ran by Eliud Kipchoge (2015, 2018), Dennis Kimetto (2013), and Wilson Kipsang (2014) all on Berlin Marathon. We computed the average speed per kilometer by dividing the distance per time and we characterized the trend (Kendall's τ) and the asymmetry for each kilometer. After the statistical study, we compared the running strategy of the marathon runners with their critical speed.
RESULTS: One of the features of this asymmetry in the speed time series is that Kipchoge, as the prior marathoners in their world record, ran more distance (66%) at a speed less-than or equal to his marathon average speed. Each of the two 21km shows the same pattern of asymmetry. The runner spent 62% of the distance at a speed less-than or equal to the average speed of the 21km.
The second feature was that he started and finished his race very fast and the trend (Kendall's τ) was positive checking that the trend of the speed of Eliud Kipchoge increased during the race (0,28). Indeed, the first and the last kilometers were run above the critical speed considered to be close to the steady state of several physiological parameters. In the last marathon world best performance, Kipchoge (2018) spent just the first kilometer and the final 195 m above his critical speed. This implies that d_acs=1195 m and that the runner spent 163 s + 31 s above his critical speed = 194 s. We deduce that Δ_d=15 m(only 6% of his d_acs) (aerobic distance capacity). In his prior 2015 Marathon world best performance, Kipchoge used nothing of his (same) d_acs. Maybe, keeping the present racing strategy but by spending more time above his critical speed, Eliud Kipchoge could improve his performance and perhaps break the 2-hour marathon barrier.
CONCLUSION: In addition to the classical view of the marathon performance analysis, the present study showed new insight and perspective in how mathematic analysis is promising given that more and more races are available on the social fitness networks.

THE COMPARISON OF PHYSICAL AND PERFORMANCE CHARACTERISTICS OF JAPANESE AMERICAN COLLEGIATE FOOTBALL PLAYERS BY DIVISIONAL LEVEL.

IGUCHI, J., HOJO, T., FUJISAWA, Y., KUZUHARA, K., YUASA, Y.

1> KYOTO GAKUEN UNIVERSITY, 2> DOSHISHA UNIVERSITY, 3> AICHI TOHO UNIVERSITY, 4> RITSUMEIKAN UNIVERSITY,

INTRODUCTION:American football is relatively popular sports in Japan. It has been reported that there are 402 teams and about 20,000 players. Some previous studies (1,2) conducted in US have examined how muscular strength, power and speed are related to winning or losing a game or becoming a starter or non-starter. The results showed that those factors described above played important roles in contributing to winning a game and/or becoming a starter. On the other hand, in Japan, there have been few researches mentioned above, especially the collegiate football by divisional level.
METHODS: We chose two division 1 teams and a division 2 team (n = 230 mean age = 20.7± 1.0 years). We collected performance and physical data, which consisted of height (cm), body mass (kg), BMI (kg/m2), 40-yd dash (seconds), vertical jump(VJ) height (cm), 1-repetitionmaximum (1RM) bench press(BP) and back squat(SQ) records (kg), relative bench press(BP_bw) and back squat(SQ_bw) records (%), and power (kg・m・s-1) , from those 3 teams. In this study, the following comparisons were made: (a) among the divisions, (b) between starters and nonstarters, (c) between backs and linemen. Independent t-tests were performed by comparing the mean scores of starters and nonstarters, and backs and linemen. One-way analysis of variance was performed by comparing the mean scores for each team. Pairwise differences were examined using Scheffe˝s method, and the alpha level was set at $p < 0.05$.
RESULTS: we confirmed the significant differences in 8, 6 and 10 out of the 10 comparisons among the divisions, between starter and non-starter, and backs and linemen, respectively ($p < 0.05$).
CONCLUSION: Overall, Division 1- players and starters had superior physical and performance characteristics such as higher height, heavier weight or stronger in BP/SQ and power. Backs and linemen were in contrast to each other, i.e. backs are smaller in height and faster in 40yrd. Linemen are heavier in weight and stronger in BP and SQ. As reported in the previous studies in US (1,2), superior physical and performance characteristics seemed to be major contributing factors in winning a game and/or becoming a starter in Japan.

COMPARISON OF PEAK FORCE AND RATE OF FORCE DEVELOPMENT DURING THE UNILATERAL AND BILATERAL HANG POWER CLEAN

HAYASHI, R.1, YOSHIDA, T.2

1: GIFU UNIVERSITY, 2: UNIVERSITY OF TSUKUBA

INTRODUCTION:Hang power clean is often used to improve force development of the lower extremities (1). Previous research has investigated the value of peak vertical ground reaction force (GRF) and rate force development (RFD) during bilateral hang power clean at many relative loads (2,3). However, no studies have yet investigated the characteristics of force development during bilateral hang power clean. This study aimed to identify the GRF and RFD during unilateral and bilateral hang power clean.
METHODS: Ten male track and field athletes performed bilateral and unilateral hang power clean (as fast as possible) at relative loads of 30%, 60%, and 90% 1RM. Under bilateral conditions, we divided the loads used in unilateral conditions by two. The height of the bar was determined by the knee angle (125°±5°). All lifts were performed on the dual force plate. The ground reaction force of the dominant leg under both conditions was sampled at 1,000 Hz. The net vertical GRF was calculated as the vertical GRF minus body weight and load for bilateral conditions, and vertical GRF minus half body weight and load for unilateral conditions. Instantaneous RFD was calculated as ΔGRF/ΔTime (0.001s). Peak values of vertical GRF and RFD were compared. Additionally, the initiation point of the pull was determined when vertical GRF exceeded the value of the lifter plus bar system.
RESULTS: The peak vertical GRF and RFD under bilateral conditions (Peak vertical GRF: 30% = 990.82±115.38 N, 60% = 1066.22±166.26 N, 90% = 1097.62±154.32 N, RFD: 30% = 6883.12±2597.43 N•s-1, 60% = 6461.46±2302.04 N•s-1, 90% = 5969.87±2312.39 N•s-1) were significantly greater than those under unilateral conditions (Peak vertical GRF: 30% = 669.40±112.69 N, 60% = 776.55±77.02 N, 90% = 801.92±66.69 N, 30% = 4812.12±2597.43 N•s-1, 60% = 3523.57±1199.37 N•s-1, 90% = 3082.52±88.37 N•s-1) at all loads ($P<0.01$).

CONCLUSION: Bilateral hang power clean rapidly exerts high forces compared with unilateral hang power clean. Therefore, when using hang power clean for training, it is considered necessary to select bilateral or unilateral hang power clean depending on the training objectives.

AN EMPIRICAL STUDY ON THE EFFECT OF KAATSU TRAINING OF ELITE HANDBALL PLAYER

CHEN, C.1,WANG, M.B.1, LI, Z.Y.2, HUANG, J.P.3
1.BEIJING RESEARCH INSTITUTE OF SPORTS SCIENCE,2.FUJIAN NORMAL UNIVERSITY,3HEBEI NORMAL UNIVERSITY

INTRODUCTION:To explore the effect of KAATSU training on strength and explosive force of lower limb of elite handball players, training result is compared with that of traditional high-intensity training, in order to improve the scientific level of strength training, and to provide certain theoretical basis and practical reference for the popularization of KAATSU training in sports teams on a large scale.
METHODS: Eighteen elite handball players were recruited and randomly divided into the experimental group and the control group according to their age. Nine players in each group were trained under KAATSU training, while the player in the control group were trained use the traditional training method. The player in the experimental group completed squat, hard pull, load-shear squat and sleigh-pushing practice under KAATSU training. Before and after 4 weeks of training, various test is performed, the contents of the tests were as follows: body composition index such as body weight, muscle mass, body fat; and biomechanical indexes such as maximum strength, vertical jump ability, isokinetic strength etc. before and after the test content, the tester and the test instrument are the same.
RESULTS: 1) After 4 weeks of KAATSU training, the weight of players increased slightly, the amount of muscle and bone increased, but there was no significant difference ($p > 0.05$). 2) after 4 weeks of KAATSU training, the maximum strength of players decreased slightly, but the difference was not significant ($p > 0.05$); 3) after 4 weeks of KAATSU training, peak torque of the left and right leg isokinetic knee flexion, the right leg isokinetic knee extension significantly increased ($p < 0.05$); 4) after 4 weeks of KAATSU training, the height of SJ, CMJ height without swing arm and the CMJ with swing arm were significantly increased ($p < 0. 05$). 5) Compared to the traditional high-intensity resistance training, KAATSU training have the effect on the body weight, body fat, muscle mass, skeletal muscle content, body fat percentage and isokinetic knee extension of the player were similarly($p>0.05$).6) the total work player were similarly ($p > 0.05$). 6) the total work of KAATSU training was significantly higher than that of traditional high-intensity resistance trai- ning ($p < 0.05$).
CONCLUSION: 1) KAATSU training can increase the body weight and muscle quantity of elite player, enhance the muscle strength and explosive force on lower extremities of athletes, especially on the training effect of weaker muscle groups; 2) Compared to the traditional high- intensity training, the training effect of the two training method is similar, and there is no difference between the advantages and disadvantages. However, with its low intensity, short interval and high repetition times, the KAATSU training will increase the total amount of training.

PERFORMANCE ASSESSMENT OF YOUTH BALL-SPORT PLAYERS

PUCSOK, J.M., RÁTHONYI, G., KOVÁCS, M., BALOGH, L.
UNIVERSITY OF DEBRECEN

INTRODUCTION:Sports performance is a complex phenomenon that may be assessed by various protocols. In general, anthropometric, body composition, spiroergometric analyses are performed, to monitor general and sport-specific performance. Athletes, especially in young ages (14-16), are very sensitive to any training stimuli, this is why it is critical to adequately measure their performance to develop high-quality training programmes.

METHODS: We selected one-hundred and ten, handball (n=30), basketball (n=40) and football (n=40) players male and female from local clubs in Hungary. To measure their performance to develop high-quality training programmes adequately age were differs from 14 to 16, they represented the elite level of their sports. They participated in performance analysis, the protocol included standard anthropometric, body composition and spiroergometric tests. We measured anthropometric, body composition and physiological parameters utilizing body fat caliper, an In Body 720 device, and a standard Bruce treadmill protocol. Although we were aware of the limitations of the Bruce protocol in elite athletes, we choose this protocol as a safer alternative for younger, inexperienced athletes.
RESULTS: As we expected, anthropometric and body composition data varied greatly due to individual differences in maturational status. After analyzing spiroergometric data with various statistical tests such as t-test, and analysis of variance (ANOVA), we found significant differences ($p<0.05$) among the groups of male football and basketball players in peak /load (Watt), peak/VO2(ml/min), peak/VCO2(ml/min), and peak/O2pulse(ml). We also found significant differences in peak/VO2(ml/min) among the group means of male handball and football players.
CONCLUSION: We concluded that in this population of male football and basketball athletes, workload, peak VO2, peak VCO2, and peak O2 pulse data is a reliable indicator of the sports performance. Peak VO2 data demonstrated significant differences among male football and handball players too. Although we have to be careful when interpreting results, prior experiences with exercise testing, biological maturation differences must be taken into account. In the future, we are planning to retest the sample population with a more sport-specific treadmill test, which integrates the various characteristics of these three sports. We hypothesized that a more specific exercise test might provide more accurate data to analyze sports performance.

RUNNING VELOCITY AT LACTATE THRESHOLD: DETERMINING FACTORS AND RELATIONSHIPS IN WELL-TRAINED AND ELITE RUNNERS.

STØA, E., RØNNESTAD, B., HANSEN, J., ELLEFSEN, S., INGJER, F., HELGERUD, J., STØREN, Ø.
UNIVERSITY OF SOUTH-EASTERN NORWAY

INTRODUCTION:Long distance running performance is mainly determined by maximal oxygen uptake (VO2max), lactate threshold (LT) and oxygen cost of running (Cr) (Pate and Kriska, 1984). The work rate at lactate threshold (LT) depends primarily on maximal oxygen consumption (VO2max) and work economy (Støren et al, 2014). LT expressed as percentage of VO2max (LT%) has in a previous study been shown to be a poor determinant of workload at LT in cyclists (Støren et al, 2014). Maximal aerobic speed (MAS), also named the

minimum velocity needed to reach VO2max, is defined as VO2max divided by Cr (Morgan et al, 1991), and shows strong correlation with running velocity for distances longer than 800 m (Lacour et al, 1990). An equation incorporating MAS and individual LT% has shown to predict workload at LT among cyclists; LTv = (LT%)VO2max/Cr (Støren et al, 2014). In previous studies among runners, the relationships between velocity at LT (LTv), and LT%, VO2max, Cr and MAS have mainly been assessed in relatively small cohorts.
The purpose of the present study was thus to examine to what extent LT%, VO2max, Cr, MAS and the equation MAS · LT% determine LTv in running.
METHODS: 75 competitive runners (37 males and 38 females) participated in the study. Performance level ranged from elite (5 males and 8 females), to national (17 males and 11 females), to regional (15 males and 19 females). The runners´ average VO2max and LTv were 63.0 ± 9.3 mL· kg-1· min-1, and 13.6 ± 2.3 km· h-1, respectively. Correlation analyses were performed based on VO2max, LT%, LTv, MAS, and Cr measurements during treadmill running.
RESULTS: There were no differences between elite, national and recreational runners in LT%, and accordingly, LT% did not correlate with LTv. However, the product of MAS and individual LT% explained 90% of LTv, outside a range of ± 0.27 km· h-1 (SEE 4%, $r = 0.95$, $p < 0.0001$).
CONCLUSION: LT% alone could not predict LTv among experienced distance runners. However, an equation incorporating the product of MAS and individual LT% was an effective tool to predict LTv among distance runners.

THE RELATIONSHIP BETWEEN FOOT-GROUND CONTACT POSITION AND MUSCLE ACTIVITY IN LEG PRESS

ARIYOSHI, K.
OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION:Leg press exercise (LP) is machine training aimed to train muscles of the thighs and buttocks. The mobilization rate of the muscle during LP varies depending on the position of the foot on the foot plate; the superior position is generally effective for the quadriceps and inferior position for the hamstrings. However, regarding internal and external rotation, it remains unclear. Therefore, this study aimed to examine the relationship between foot-ground contact position and muscle activity during LP.
METHODS: Subjects were 8 healthy male student athletes (age: 19.8 ± 1.0 years; height: 170.8 ± 4.3 cm; weight: 68.4 ± 6.0 kg) who gave informed consent to participate in this study. Hammer Strength Select Seated LP machine (Life Fitness) was used. Measurements were performed in the following 5 foot positions: 1) center, 2) superior - 15 cm superior to the center, 3) inferior - 15 cm inferior to the center), 4) 30° external rotation at the center, and 5) 30° internal rotation at the center. The foot width was set as the shoulder width and each condition was performed 5 times at a load of 20 repetition maximum (RM). During the exercise, images were recorded from the lateral view using a digital video camera and surface electromyogram (EMG), which were measured at the gluteus maximus, rectus femoris (RF), vastus lateralis, vastus medialis, biceps femoris (BF), and semitendinosus (ST) muscles. Based on the images obtained, LP was classified as 90° aspect from the knee joint maximal flexion position (aspect ①) and maximal extension aspect from knee joint at 90° (aspect ②). We calculated the electromyographic root mean square (RMS) values of each aspect and normalized them by dividing by the RMS value at each maximal voluntary contraction. One-way repeated analysis of variance was performed with Bonferroni post hoc analyses to compare measurement values at 1) center, superior, and inferior and 2) center, external rotation position, and internal rotation position ($p<0.05$).
RESULTS: Regarding aspect ①, significant differences were noted for RF center (49.2% ± 45.3%) and superior (25.1% ± 36.1%), superior (25.1% ± 36.1%) and inferior (59.0% ± 34.6%), ST center (6.0% ± 2.3%) and superior (16.6% ± 7.9%), center (6.0% ± 2.3%) and inferior (4.2% ± 1.9%), and superior (16.6% ± 7.9%) and inferior (4.2% ± 1.9%). Regarding aspect ②, significant differences were noted for BF center (11.7% ± 5.7%) and superior (20.8% ± 9.5%), superior (20.8% ± 9.5%) and inferior (8.4% ± 4.0%), and center (11.7% ± 5.7%) and external rotation (14.0% ± 9.0%) ($p<0.05$).
CONCLUSION: In the case of 20 RM LP, hamstring mobilization was increased when the foot position was superior on the foot plate. Also, mobilization of the quadriceps was increased when the foot position was inferior on the foot plate.

THE EFFECT OF INTERMITTENT HYPOXIC RESISTANCE TRAINING ON MUSCLE HYPERTROPHY AND STRENGTH

ATTWATERS, M.H., HUNTER, S.
LONDON SOUTH BANK UNIVERSITY

INTRODUCTION:The maintenance of muscle mass can facilitate physical tasks of daily living (Landers et al., 2001), improve markers of health and reduce all-cause mortality (FitzGerald et al., 2004). Guidelines state that moderate to heavy mechanical loading (>65% 1-repetition maximum [1RM]) is required to achieve improvements in muscle strength and hypertrophy (ACSM, 2009). Recent literature has demonstrated that low-load (20-50% 1RM) resistance training combined with hypoxia can promote favourable alterations in muscle adaptations (Scott et al., 2014). The aim of this study was to investigate muscle hypertrophy and strength responses to 4.5 weeks of low-load (20% 1RM) resistance training combined with normobaric hypoxia.
METHODS: Eight healthy adults (5 male: 21.2±1.3 years, 178.9±9.7 cm, 79.7±12.5 kg and 3 female: 21.7±0.6 years, 169.2±4.5 cm, 58.2±11.0 kg) were recruited to participate in this study. A single-blind within-subjects design was employed in which one leg (dominant or non-dominant) was resistance-trained under hypoxic conditions (FIO2 = 13%; HYP) and the contralateral leg was resistance-trained under normoxic conditions (FIO2 = 21%; NORM). All resistance training variables were held constant. Thigh muscle mass & unilateral concentric 1RM strength of the knee-extensors for each leg was assessed in normoxic conditions before and after the training protocol.
RESULTS: There were no significant differences ($P>0.05$) in thigh muscle mass after resistance training in either HYP (9.4±2.3 kg to 9.4±2.2 kg) or NORM (9.4±2.3 kg to 9.4±2.2 kg). There was no significant interaction between condition and time ($P>0.05$). Unilateral knee-extension 1RM significantly increased ($F(1,7) = 9.59$, $P=0.03$) after resistance training in both HYP (55.6±16.0 to 59.0±18.7 kg) and NORM (54.4±17.0 to 58.0±18.4 kg). There was no significant interaction between condition and time ($P>0.05$).
CONCLUSION: The present findings suggest that the application of systemic hypoxia (FIO2 = 13%) during 4.5 weeks of low-load (20% 1RM) resistance training does not significantly increase muscle hypertrophy or strength compared to that of normoxia training. Nonetheless,

significant improvements in muscle strength were observed after resistance training in both conditions, despite the use of relatively low exercise loads (20% 1RM). This suggests opportunities for strength development in those with low initial muscle force capacity.

THE RELATIONSHIP BETWEEN FUNCTIONAL SINGLE-LEG HOP STABILIZATION TEST AND FMS- TEST IN MARTIAL ARTS AND TEAM SPORT YOUNG MALE ATHLETES.

PEDAK, K.1, RANNAMA, I.1, PORT, K., BAZANOV, B.1

TALLINN UNIVERSITY

INTRODUCTION:The aim of this study was to compare the functional movement performance ability and functional stabilization ability of martial arts and athletes from team sport. Participants was competition level young athletes of Team sport belonged the players from basketball, handball, volleyball. Martial arts belonged judo, taekwondo, karate . Choose groups like this becomes from movement patterns differences. Team sport needs multi- directional speed and variables movements for a successful play. The team sport players using more frequent changes of direction, acceleration, deceleration and sudden jumps (2). Martial arts using a series of movement sequences involving punching, kicking, blocking, jumping, twisting and leaping performed at high intensity and must concentrate alone on the opponent (1).
METHODS: 19 martial arts athletes (17,6±2,2a years; height=177,6±6,7cm and BMI=24,4±3,7) and 45 team sport (age =16,27 ± 1,7 years; height=183,2± 6,6 cm and BMI=23,5 ± 3,8) . Participants were screened using the functional movement screen protocol that comprised the seven movement patterns. Each participant was videotaped. The videos were then analized using FMS 100-point scale what is more indicative and can be scored with a high level interrater reliability in trained rates. The Dynamic Postural Stability Index (DPSI) and the directional components (medial-lateral, anterior-posterior, and vertical) after a jump landing one leg was measured by Kistler force plates. Total Dynamic Stability Index (DSI) is calculated as the composite of the individual stability components, given by: DPSI = √ (MLSI2 + APSI2 + VSI2). All statistical analysis was computed using the IBM SPSS Statistics (version 23.0).
RESULTS: The mean composite FMS 100-point scale of martial arts athletes was 55,1±9,3 and team sports athletes 45,0±6,4. Martial arts athletes shows higher score in deep squat, active straight-leg raise ($p<0,05$) and trunk stability push-up test. There was not significant differences between athletes groups stability test results. Correlation between FMS score and the directional components and DPSI martial arts athletes shows better results(DPSI $r^2= 0,30$ vs $r^2= 0,00$; MLSI $r^2= 0,27$ vs $r^2 = 0,00$; APSI $r^2 = 0,22$ vs $r^2 = 0,00$; VSI $r^2 = 0,31$ vs $r^2 = 0,00$).
CONCLUSION: The main results of this study indicate low FMS score in both groups. The team sport athletes have more problems with muscles of the ankle and hip mobility and trunk muscles stabilizing than martial artists. FMS test 100- point scale correlation between the directional components and DPSI exist and this test looks useful to indicate sport-specific problems but need more further research.

RELATIONSHIP BETWEEN TOE GRIP STRENGTH AND SINGLE-LEG JUMP AND DOUBLE-LEG JUMP IN KENDO ATHLETES

SANOMURA, M.1, WAKAMATSU, K.2, YAMAMOTO, A.1, SAHO, Y.1

1: FACULTY OF MEDICAL TECHNOLOGY, TEIKYO UNIVERSITY , 2: J. F. OBERLIN UNIVERSITY

INTRODUCTION:Kendo (a traditional Japanese martial art) is a combat sport that is performed barefoot; it includes play characteristics such as attacking (e.g., swinging the bamboo sword downward) while simultaneously pushing off forcefully with the back foot. The toe grip strength of the back foot is thought to contribute to the push-off force. This study aimed to examine the relationship between toe grip strength and the distance of a single-leg jump with the back foot and front foot and double leg jump in kendo athletes.
METHODS: 1. Subjects
Study participants were 26 college kendo athletes (20 males (mean ± SD): age 19.3 ± 1.1 years, height 169.4 ± 5.0 cm, body weight 65.1 ± 9.1 kg, Kendo experience 11.5 ± 1.3 years; 6 females: age 19.3 ± 1.1 years, height 158 ± 3.7 cm, body weight 54.3 ± 6.0 kg, Kendo experience 11.9 ± 0.7 years).
2. Measurements
1) Toe grip strength
Toe grip strength was measured with a toe-grip dynamometer (T.K.K. 3361, Takei Scientific Instrument Co., Ltd, Niigata, Japan). Maximum effort isometric finger flexion was taken in the standing position. The parameters were calculated as the average of two trials.
2) Single-leg jump
A single-leg jump was defined as performing a single-leg stand with toes on the line, then making a single-leg jump as far as possible with the standing leg. The distance was measured from the start line to the heel of the landing leg. The parameters were calculated as the average of two trials using the back foot (push-off foot) and the front foot.
3) Double-leg jump
A double-leg jump was defined as performing a double-leg stand with toes on the line, then jumping forward as far as possible with both legs. The distance was measured from the start line to the heel of the landing leg. The parameters were calculated as the average of two trials.
3. Analysis
Pearson's correlation coefficients were calculated to examine the relationship between the toe grip strength of the back foot or front foot and single-leg jumps with back foot and front foot or double-leg jump. Significance levels were set at $p < 0.05$.
RESULTS: The toe grip strength of the back foot was significantly correlated with a single-leg jump with front or back foot and a double-leg jump ($r = 0.746$, $p < 0.001$; $r = 0.729$, $p < 0.001$; and $r = 0.606$, $p = 0.001$, respectively). The toe grip strength of the front foot was not significantly correlated with any parameter.
CONCLUSION: This study suggests that the toe grip strength of the back foot (push-off foot) is significantly related to the distance of both a single-leg jump with front or back foot, and to a double-leg jump. On the other hand, the toe grip strength of the front foot is not significantly related to either form of single-leg jump or to the double-leg jump in terms of distance. Thus, toe grip strength with the back foot may be particularly related to the push-off force with the back foot among kendo athletes.

EXERCISE INTENSITY ANALYSIS OF HIGH-INTENSITY INTERVAL TRAINING

LIU, C.M., CHENG, C.H.

CHANG JUNG CHRISTIAN UNIVERSITY

INTRODUCTION:High-intensity interval training (HIT) has become a popular training program. It may be a feasible and effective strategy for improving health fitness and athletic performance. Even though there are many studies indicate HIT is effective and time saved, but there is still no direct evidence of the exercise intensity in HIT. This study explores changes in exercise intensity at different phases in the single bout of HIT process.
METHODS: Twelve university-level male rugby athletes volunteered for the study. Written informed consent was obtained from all the subjects before the experiment begin. All the subjects were required to participate in high-intensity interval training with 15 seconds of all out of sprint run and 30 seconds of rest, 8 cycles. Throughout the process, they wore the POLAR watch to record their heart rate, and RPE was recorded at each rest phase. In addition, blood was taken to detect blood lactate concentration during the rest phases of the second, fourth, sixth, and eighth cycles and at three, five, ten, fifteen, and thirty minutes after training(POST-min). Repeated measures one-way analysis of variance was used to test the blood lactate, %HRR, and RPE values, respectively, derived at different phases during high-intensity interval training. A level of .05 was used to indicate statistical significance.
RESULTS: Study results showed that the blood lactate concentration was 3.02 ± 0.85 mmol/L before training, then the measurements enhanced continuously until post-exercise 3min, and the minimum value was 4.19 ± 0.66 mmol/L(first interval), maximum value was 7.74 ± 0.94 mmol/L (eighth interval), while the mean value was 6.14 ± 1.48 mmol/L during training. After training, maximum blood lactate concentration was 8.29 ± 0.90 mmol/L (POST-3min), minimum value was 4.36 ± 1.51 mmol/L(POST-30min), while the mean value was 6.84 ± 1.53 mmol/L. Maximum heart rate was 162.17 ± 10.39 bpm at the seventh interval, the mean value was 150.99 ± 13.30 bpm during training. Minimum %HRR was 47.52 ± 6.93%(first interval, moderate), the maximum value was 74.83 ± 6.96%HRR(seventh interval, vigorous), while the mean value was 66.99 ± 9.29%HRR(vigorous). Minimum RPE(Borg scale 0–10) was 4.54 (first interval, somewhat hard), the maximum value was 9.00 ± 0.55 (eighth interval, very, very hard), and the mean value was 7.03 ± 1.75 during training(very hard).
CONCLUSION: According to the results of this study, we proved that in the process of HIT, blood lactate concentration continued to be produced, reaching the effects of high-intensity training. During high-intensity interval training, the exercise intensity was in the vigorous stage, with the intervals increased, the perceived exertion enhanced continuously until very, very hard by participants. We suggested that further study in HIT can focus on the effect of different rates of exercise recovery time and different sets.

EFFECTS OF TRX® TRAINING IN MUSCLE STRENGTHENING AND MUSCLE FIRING IN UPPER EXTREMITY

LIN, H.T., HUANG, J.J.

KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION:Athletes have better muscle strength to improve athletic performance (1), while older people have better muscle strength to avoid falls and improve quality of life (2). Therefore, it's important for most people to have proper muscle strength training, Total Body Resistance Exercise (TRX•), is the one of the suspension training that is popular recently. The unstable training instrument may have different training mechanism to improve muscle strength from traditional resistance training. Therefore, the purpose of this study is to investigate the effect of TRX training in muscle strengthening in upper extremity.
METHODS: Thirty-two collegiate students were randomly divided into TRX group and traditional resistance training group (RT). Both of these two groups had similar muscle strengthening program by using TRX (TRX group), and traditional training way by using dumbbell and barbell with similar training intensity (6-10 RM). The muscle strengthening program comprised four different exercises focused on the shoulder biceps and triceps training. For each exercise, participates carried out 3 sets of 8 repetitions during eight weeks, twice a week's training. The dynamometer was used to measure the isometric shoulder flexion and extension joint torque to evaluate the effect of muscle strengthening. Moreover, the decomposed electromyography (dEMG) was used to detect the muscle motor unit firing change at 30% and 50% of muscle maximum voluntary contraction (MVC) before and after training.
RESULTS: The results showed that muscle strength both in shoulder flexion and extension torques were significantly increased after eight weeks training in both groups ($p<0.001$), and had similar improved level between groups ($p=0.34$). The motor unit mean firing rate of biceps and triceps muscle contraction at different level of MVC did not change before and after training. After 8 weeks training, the decreased rate of the mean firing rates at recruitment as functions of the recruitment threshold was significant increase in both training groups (TRX group: $p=0.027$ at 30% MVC & $p=0.014$ at 50% MVC; RT group: $p=0.039$ at 30% MVC & $p=0.021$ at 50% MVC). The change rate in TRX groups was significant larger than RT group after 4 week's training ($p=0.032$ at 30% MVC & $p=0.043$ at 50% MVC), but not found after 8 weeks' training ($p=0.083$ at 30% MVC & $p=0.146$ at 50%MVC).
CONCLUSION: This study found that TRX training could have similar muscle strengthening effect to traditional training. Both training could alter the muscle firing mechanism, but the TRX training may have better effect in the first four weeks' training.

EFFECT OF ARTIFICIAL CO2 RICH COLD WATER IMMERSION ON REPEATED CYCLING WORK EFFICIENCY AND SPRINT PERFORMANCE

FUKUOKA, Y., YOSHIMURA, M., HOJO, T., NAKAMURA, M.

DOSHISHA UNIVERSITY

INTRODUCTION:The purpose of the present study investigated the acute effects of cold water immersion (20°C) with higher CO2 concentration (>1000ppm; CCWI) intervention on sublingual temperature (Tsub), blood lactate ([La]b), heart rate (HR), aerobic cycling work efficiency (WE) and anaerobic Wingate performance (WAnT) in comparison with cold tap-water immersion (20°C; CWI) and passive recovery (PAS).
METHODS: Fifteen subjects completed three testing sessions separated by 1 week; each trial consisted of the 1st WE and WAnT, 20-min recovery interventions (randomize: CCWI, CWI, and PAS) before repeating 2nd WE and WAnT. Aerobic WE and anaerobic WAnT were measured as the changes in WE during 50%VO2max exercise and WAnT from 1st bout to 2nd bout. HR, Tsub and [La]b were recorded throughout the testing sessions.
RESULTS: There was a significant decline in the WE after PAS (mean (SD) −1.04% (0.59%)) compared with the CCWI trail (−0.66% (0.46%)) not significance at CWI trial (−0.94% (0.42%)). Whereas WAnT were also reduced from 1st bout to 2nd bout, this reduction was unaffected by water immersion (WI). Reduction of Tsub was significantly larger after CCWI (0.25°C (0.15°C)) compared with CWI (0.20°C (0.08°C)) and

PAS (0.05°C (0.18°C)), and then CCWI maintained lower Tsub until the 2nd WAnT. Although an increased [La]b after the 1st WAnT was not different among three trails, a significantly reduced [La]b was mostly achieved at CCWI (7.8 mM (0.4)) rather than CWI (8.7 mM (0.7)) and PAS (10.2 mM (1.1)). Likewise, the reduction in HR following WI was the largest at CCWI at other conditions, this reduction of HR was continued until the 2nd WE.
CONCLUSION: These findings indicate that CCWI is an effective intervention for maintaining repeated cycling work efficiency which is associated with reduced blood lactate and heart rate. Otherwise, water immersion may not be beneficial effects on the reduction in anaerobic performance even utilizing CO2.

THE RESULT OF CROSSFIT TRAINING METHOD FOR SHANGHAI FEMALE WEIGHTLIFTING TEAM

CHEN, S.

SHANGHAI RESEARCH INSTITUTE OF SPORT SCIENCE

INTRODUCTION:This article explores about the training of athletes in female weightlifting program by participating in CrossFit training, and provides an experimental basis for adding new training methods for weightlifting projects.
METHODS: After 8-weeks CrossFit training to 6 female weightlifters, texts were taken before and after the exercise respectively including body composition, special fitness, blood biochemical test, 30sec anaerobic power test and heart rate.
RESULTS: The result turned out that after 8-weeks CrossFit training, (1) the percentage of body fat of athletes reduced by 3.47%（P>0.05）; (2) the maximal power of 30sec anaerobic power test increased by 6.87%（P<0.05）, the mean power of 30sec anaerobic power test increased 6.95%（P<0.05）, the min power of 30sec anaerobic power test increased by 22.45%（P<0.01）, the rate of fatigue of 30sec anaerobic power test decreased 7.38%（P<0.01） and the heart rate declined 13.9%（P<0.05） of 2 minutes after exercise.
CONCLUSION: （1） 8-weeks CrossFit training can effectively enhance female weightlifters' anaerobic energy contribution system and glycolysis energy contribution system, elevated cardiopulmonary function and the level of heart rate recovery; （2）the enhancement of aerobic and anaerobic capacities and the reduction of content of body fat depend on various CrossFit paired workouts. Specific training system should be make in line with different exercise and purpose.

LONG-TERM EFFECT OF TWO-TYPE EXERCISE CAPACITY ON MUSCLE STRENGTH AND ENDURANCE PERFORMANCE IN ELDERLY ADULTS

MOHAMMED, R.

UNIVERSITY OF SULAIMANI

INTRODUCTION:Aging is related with loss in both muscle mass and the metabolic quality of skeletal muscle. A major part of these changes is related with an age-related reduction in the level of physical activity and might be balanced by endurance training (ET) and resistance training (RT).
Since both muscle strength and aerobic power diminish with age, we explored what type of training may be best for upgrades in physical performance in the elderly. In detail, we wanted to know whether systematic ET can increase muscle strength and/or whether systematic RT can augment the aerobic power of healthy elderly adults.
METHODS: Twenty-four volunteers (9 women, 15 men) were recruited for the study and randomized into three groups: 8 persons undertook a continuous 24-weeks ET program, 8 undertook a continuous 24-weeks RT program and 8 served as a control group. All persons performed a cycling test to measure aerobic power (VO2max) and maximum workload (VO2max) before and after the training period. Maximum strength was determined from one repetition maximum (1-RM).
RESULTS: After 12-weeks of RT, maximum strength increased by an average of 11% for leg press ($P < 0.01$), 19% for bench press ($P < 0.01$) and 23% for bench pull ($P < 0.001$); ET showed no effect on maximum strength except for the 1-RM in bench pull. Aerobic power improved by 4% in the ET group and by 1.5% in the RT group, neither of which was significant. Maximum workload improved significantly by 26% in the ET group ($P < 0.001$) and by 4% in the RT group ($P = 0.05$). ET resulted in a significant 3.3% reduction of body fat ($P < 0.05$), whereas only RT increased lean body mass by 1.0 ± 0.5 kg.
CONCLUSION: RT leads to a genuine increase in lean body mass and muscle strength in healthy elderly adults and is therefore the best method for treatment of amyotrophia. ET appears to be the most efficacious training mode for maintaining and improving maximum aerobic power in the elderly and should be viewed as a complement to RT. The loading intensity to promote hypertrophy should approach 60–80% of 1-RM with an exercise volume ranging from 3 to 6 sets per muscle group per week of 10–15 repetitions per exercise. ET should be performed on two days per week controlled by a heart rate according to 60% of VO2max and an exercise volume ranging from 30 to 60 minutes per week.

UPPER- AND LOWER-BODY STRENGTH, POWER AND VELOCITY CHARACTERISTICS IN ELITE RUGBY LEAGUE PLAYERS AND THE INFLUENCE OF PLAYING STANDARD: A CASE STUDY

FERNANDES, J.F.T., DANIELS, M., MYLER, L., TWIST, C.

HARTPURY UNIVERSITY

INTRODUCTION:This study compared the load-velocity and load-power relationships among 1st team (n = 26, age 22.9 ± 4.3 years), academy (n = 23, age 17.1 ± 1.0 years) and scholarship (n = 16, age 15.4 ± 0.5 years) Super League rugby league players.
METHODS: Participants completed assessments of body mass, sum of skinfolds, maximal upper- and lower-body strength (1RM) and peak velocity and power at 20, 40, 60 and 80 kg during bench press and squat exercise, in a randomised order.
RESULTS: Body mass was likely to most likely different across playing standards with sum of skinfolds likely different between 1st team and academy players and unclear differences between all other comparisons. Bench press and squat 1RM were different across playing standards, except squat between 1st team and academy where differences were possible. Peak velocities during bench and squat were likely and most likely greater in the higher playing standards, except for squat at 20 and 40 kg. Peak power reflected the playing standard (i.e. higher peak powers in the better playing standards) for all loads and exercises. For all three groups, velocity was correlated to optimal bench press power ($r = 0.514$ to 0.766, $P < 0.05$), but only 1RM was related to optimal power ($r = 0.635$, $P < 0.05$) in the scholarship group. Only squat 1RM in the academy group was related to optimal squat power ($r = 0.505$, $P < 0.05$).
CONCLUSION: These data indicate that peak velocity and power are pathways for progression to 1st team in academy and scholarship rugby league players. Furthermore, the correlations between 1RM and velocity with optimal power provide directions training in these rugby league players.

THE DIFFERENT EFFECT OF TREADMILL EXERCISE AND WHEEL RUNNING EXERCISE ON MUSCLE STRENGTH IN MOUSE

KIM, Y.J.1, CHO, S.H.3, SEONG, J.K.1,2, SONG, W.3,4

SEOUL NATIONAL UNIVERSITY

INTRODUCTION:Regular physiological activity is very important to counteract disease like obesity, diabetes and metabolic syndrome. The Treadmill Aerobic Exercise(TE) required to the appointed time and strong intensity and Wheel Running Exercise(WE) proceeded with voluntary enhanced activity in mice. Here, we show that mice exercised by Treadmill and Wheel Running for 8 weeks have different physiological effects.
METHODS: For adaptation to the Treadmill, TE group mice put the lane on to familiarize for 30 minutes. The speed of running increased from 5m/min for 10 minutes to 9m/min for 20 minutes. After the 1-week adaption, the TE group was performed to run from 20m/min for an hour for 8 weeks. An incline of Treadmill machine was gradually raised from 5° to 15° from 5-week exercise periods. WE group performed voluntary wheel running exercise for 8 weeks.
RESULTS: During exercise, TE and WE group have decreased Body weight compared to the control group(No exercise, CON). Interestingly, Food Intake per day of WE has the highest than TE and CON although WE have the lowest body weight. Also, Grip strength per body weight has a significant difference in WE groups compared to others after exercise. After Exercise, TE and WE group have lower fat mass than CON. In Lean mass, there was no significant difference between groups. After anesthetized, we measured the weight of fat tissues (eWAT, iWAT, BAT) and muscle tissues (GAS, SOL, TA, EDL). We found that similar to Body composition data, TE and WE group have lower fat weight compared to CON group, but not muscle weight. We investigated histological observations of eWAT (epididymal white adipose tissue). The result shows that adipocyte size decreased in exercise groups compared to CON. In soleus muscle, TE and WE significantly increased expression of PGC1 α compared to CON. We found that in soleus muscle, Troponin 1-SS protein had increased pattern in WE compared to CON and TE groups. TE group also increased Troponin 1-FS expression compared to other groups.
CONCLUSION: We induced that Treadmill exercise protocol enhances muscle strength by incline when they exercised and Wheel Running Exercise protocol improves voluntary physical activity ability. Interestingly, WE group has lower body weight than other groups although WE group eat more. This data show Wheel Running Exercise can spend more calories than Treadmill Exercise. Our results also support that after both exercises, Fat mass decreased, but not lean mass. We found that similar to decreased fat mass, adipocyte size decreased after two types of exercise. We also discovered that WE group increased mitochondrial biogenesis, in soleus muscle, Troponin 1-SS protein had increased pattern in WE compared to CON and TE. TE group also increased Troponin 1-FS expression compared to other groups. Results suggest that Treadmill and Wheel Running Exercise have a significantly different molecular mechanism in skeletal muscle.

MECHANICAL AND NEUROMUSCULAR PROPERTIES OF ANTAGONISTIC MUSCLES ON THIGH AND LEG IN MALE SPRINTERS, MIDDLE DISTANCE RUNNERS AND LONG DISTANCE RUNNERS.

TSUNODA, N.1, HIRATSUKA, K.1, MIYAZAKI, D.1, SIMUNIC, B.2, DJORDJEVIC, S.2

1: KOKUSHIKAN UNIVERSITY , 2: UNIVERSITY OF PRIMORSKA

INTRODUCTION:Recently, tensiomyography has been used as a tool to measure the mechanical and neuromuscular properties of selected muscles in athletes in an effortless and non-invasive way (1). There are not study for mechanical and neuromuscular properties of antagonistic muscles on lower limb in athletes. Therefore, in this study, it is to clarify the mechanical and neuromuscular properties of antagonistic muscles on thigh and leg in male sprinters, middle distance runners and long distance runners.
METHODS: Eighty-one male collegiate athletes of sprinters (SP; n=29, 20.2±1.9yrs), middle distance runners (MDR; n=19, 20.5±1.2yrs) and long distance runner (LDR; n=33,19.9±1.4yrs). The mechanical and neuromuscular properties of antagonistic muscles for rectus femoris (RF) and biceps femoris (BF) in thigh, and tibialis anterior (TA) and gastrocnemius medialis (GM) in leg were assessed by tensiomyography (TMG method). Contractile properties of delay time (Td) contraction time (Tc) and maximal displacement of the muscle belly (Dm) were analyzed in each groups. Antagonistic muscles ratio (Ant.R) of RF to BF (RF/BF) and TA to GM (TA/GM) were analyzed in each groups.
RESULTS: Td of RF, BF and GM in SP were obtained significantly lowest values among the groups. Tc of RF in LDR and MDR observed long contraction time. Whereas, Tc of RF in SP was significantly shorter times than that of MDR and LDR. Dm of BF and GM in SP were significantly lower value than of MDL and LDR. Td of Ant.R for TA/GM in SP was significantly higher value than that of MLD and LDR. And also MDR and LDR were showed same ratio. In LDR, Tc of Ant.R for RF/BF obtained lowest value among the groups. And Tc of Ant.R for RF/BF in SP and MDR were showed same values. Whereas, Tc of Ant.R for TA/GM were not significantly different in among the groups. Dm of Ant.R for RF/BF in SP was significantly higher value than that of MDL and LDR.
CONCLUSION: In this study, mechanical and neuromuscular properties on RF, BF and GM in sprinters were significantly differed to the middle distance runners and long distance runners. Also, the antagonistic of RF to BF on Tc and Dm in long distance runners showed significantly lower values compared to the sprinters and the middle distance runners. From these results, it was considered that mechanical and neuromuscular properties of antagonistic muscles may reflect to the muscle fiber composition in athletic events.

COMPARISON OF PHYSIOLOGICAL STRESSES BETWEEN THE FRONT AND THE REAR SADDLE CYCLIST IN A TWO-HOUR ENDURANCE TANDEM-BICYCLE RACE

ONODERA, S., HAMADA, H., ARATANI, Y., YOSHIDA, N., TAMARI, Y., WADA, T., SAITO, T., TSUCHIDA, Y., HAYASHI, S., ISHIMOTO, Y., WAKIMOTO, T., MATSUO, K., YAMAGUCHI, H., YOSHIOKA, A., KATAYAMA, K.

1.KUMW , 2.HIT , 3.SCC , 4.FCU , 5:KIU , 6.KUSW , 7.NU , 8:NIFS

INTRODUCTION:We have reported that during tandem-bicycle race, the physiological stresses of front saddle cyclist are greater than those of the rear saddle cyclist. In the present study, we analyzed physiological stresses of the front and the rear saddle cyclist by dividing into uphill and downhill part in a two-hour endurance tandem-bicycle race.
METHODS: Twelve healthy Japanese adult males (front saddle cyclists (n=6): age, 25 ± 5 years, height, 172.3 ± 5.3 cm; body weight, 66.6 ± 6.7 kg; and peak oxygen uptake, 44.9 ± 5.0 ml/kg/min) and rear saddle cyclists (n=6): age, 25 ± 5 years; height, 170.8 ± 6.9 cm; body weight, 77.0 ± 13.9 kg; and peak oxygen uptake, 45.4 ± 6.5 ml/kg/min) participated in a five-hour endurance race held in OKAYAMA International Circuit (3.7km around). The course was divided into two parts by undulation, that is, one is on an uphill part (A), and the other

is a downhill part (B). Heart rate was measured by using heart rate monitor (Polar). Individual physiological stresses were evaluated by the pre-determined HR- VO2 relationship for each subject The ambient air temperature and relative humidity were 32.1±1.6°C and 39.6±0.4%, respectively. All of the data were statistically analyzed by SPSS ver.23 for Mac.
RESULTS: Each pair performed 12 laps around a 3.7-km track in 2 hours. The mean values of relative physiological stresses of the front and the rear saddle cyclists (six pairs) at two parts were front; 77%±4.4, rear; 72%±5.0 in A, and front; 76%±5.2, rear; 73%±6.0 in B, respectively. In the comparison of the difference in relative physiological stresses between A and B, those in front cyclists were significantly greater than in rear cyclists.
DISCUSION:
These results indicate that the relative physiological stress of front saddle cyclist is greater than that of rear saddle cyclist during uphill parts. These differences would be caused by handle, brake and gear operations and wind pressure.
CONCLUSION: The relative physiological stress of the front saddle cyclist during uphill parts would be greater, when compared to that of the rear saddle cyclist even in the two-hour tandem-bicycle endurance race.

EFFECTS OF ECCENTRIC EXERCISE-INDUCED MUSCLE DAMAGE ON MUSCLE-TENDON BEHAVIOUR FOR KNEE EXTENSORS AND ELBOW FLEXORS.

LIN, K.X.1, WU, S.H.1, LIN, M.J.1, CHEN, H.L.1, CHEN, T.C.C.2

1DEPARTMENT OF PHYSICAL EDUCATION, HEALTH AND RECREATION, NATIONAL CHIAYI UNIVERSITY, CHIAYI, TAIWAN,DEPARTMENT OF PHYSICAL EDUCATION, 2NATIONAL TAIWAN NORMAL UNIVERSITY, TAIPEI CITY, TAIWAN.

INTRODUCTION:Recent study (Lin, et al., 2015) reported that increasing in the number of eccentric contractions of knee extensors (KE, 60 sets) is one times more than elbow flexors (EF, 30 sets), producing more significant changes in muscle damage, and may have similar results to the exercise-induced muscle damage (EIMD) degree of EF (Chen et al., 2013). No studies have investigated the changes of muscle tendons in upper and lower limbs after EIMD.
METHODS: Ten untrained young men used the non-dominant KE for a bout of 60 sets of maximal eccentric exercise (MAX1). After MAX1 for seven days, All subjects continued to perform 30 sets of maximal eccentric exercise (MAX2) in one bout of EF. The two bouts of testing included before MAX (PRE), MAX (D0), and after MAX period observations (D1-D5). The changes in maximal voluntary isokinetic concentric torque (ISOK), muscle soreness (SOR), joint range of motion (ROM), limb circumference (CIR), and ultrasound image (muscle-tendon length) were measured.
RESULTS: After MAX, there was no significant difference in the degree of muscle damage and the length of the muscle-tendons between the upper limb and the lower limb muscle groups ($p>.05$).
CONCLUSION: The indicators of muscle damage and the length of the muscle-tendons caused by MAX in the upper and lower limbs were not significantly different for the comparison of the upper and lower limbs. The inference was re-examined (Chen et al., 2013; Lin et al., 2015), but the changes of upper limb muscles were greater after centrifugation than the lower limb muscles.

EFFECT OF TRAINING AMOUNT AND INTENSITY ON COUNTER-MOVEMENT JUMPING PERFORMANCE IN FEMALE COLLEGIATE VOLLEYBALL PLAYERS

YOKOZAWA, S., HIRATSUKA, K., IIDA, S., TANAKA, S., YOKOZAWA, T., TSUNODA, N.

KOKUSHIKAN UNIVERCITY

INTRODUCTION:In previously, vertical jumping performance was useful to evaluate the neuromuscular fatigue in various ball games. For example, jumping height was significant reduced over the course of the three matches in 3 days on female handball player (1). Whereas, the small decreases on counter-movement jumping performance was observed in rugby players during training period (2). However, the effect of training amount and intensity to the jumping performance in ball game was not cleared. Therefore, the purpose of this study was to investigate the effect of training amount and intensity on counter-movement jumping performance in female collegiate volleyball players.
METHODS: Twelve female collegiate volleyball players (19.2 ± 1.2 yrs) with no physical disabilities were participated in this study. The jumping height in counter-movement jump(CMJ) was measured 10 times (before-training period = BTP: 2 times, training period = TrP: 4 times, taper period = TaP: 4 times) using jump mat (Applied Office co.). The ratio of jumping height in each tests to BTP were calculated in all the subjects. The total training amount and intensity on each week in during volleyball were recorded 8 weeks (TrP: 4 weeks, TaP: 4 weeks) using active style Pro HJA-750c (OMRON co.) method. Furthermore, record of training amount was classified intensity in low, medium and high.
RESULTS: The jumping height in TrP showed significant declined than that of BTP. Whereas, the TaP was showed almost same jumping height compared to BTP. The relationship between ratio of jumping height and training amounts during volleyball training showed negative correlations in all the intensity.
CONCLUSION: In this study, the jumping performance reduced in TrP. After that, jumping performance was recover to the BTP level. Also, training amounts in three intensities during volleyball training were correlated to the ratio of jumping height. From these results, it was considered that counter-movement jumping performance on female collegiate volleyball players may decline by the increases of training amount regardless of training intensity.

CONTRIBUTION SOMATOTYPES INDICATORS IN PREDICTING PERFORMANCE IN ELITE MALE VOLLEYBALL

NOUTSOS, K., GIANNOPOULOS, N., BAYIOS, I.

NATIONAL & KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION:The athlete's somatotype provides information about the anthropometric profile by combining fatness, skeletal muscle mass, linearity and influences the level of sport performance. The aim of this study was to investigate the contribution of somatotype in predicting performance in attack in elite male volleyball players.
METHODS: The sample consisted of 68 elite male volleyball players (age = 28.57 ± 9.45 years). Measured parameters included height, weight, width of five skinfolds (biceps, triceps, subscapular, supraspinale and calf) two biepicondylar bone breadths (humerus, femur) and three girths (biceps flexed and tenced and calf). The somatotype was determined according to the method of Heath & Carter (1990). Performance in attack was assessed using a 5-point scale (0-4) (2). A total of 2454 attack actions deriving from 24 video-recorded volleyball games of the Greek National League was analysed. To assess performance in attack (PA) the formula PA= (S/P)*100 was used, where S referred to the sum of all rated attack actions and P was the sum of the attack actions rated with grade 4, suggesting an excellent attack action. The dependency of performance in attack on somatotype was tested via multiple linear regression, with the three somatotype components as predictors
RESULTS: The mean somatotype of players was central (2.90-2.16-3.10)(Fig 1).The mean performance of players in attack was 67.95 ± 9.45. Significant predictors of performance are (in order of relative importance) ectomorph (β=0.716), mesomorph (β=0.360) and endomorph (β=0.280).
CONCLUSION: The present study is in agreement with the study of Viitasalo (1982), which examined the relation of physical dimensions and performance in Volleyball. Our results also support previous evidence about the decisive advantage of players with longer lower extremities in jumping and attacking (3). In conclusion, the greater ectomorphic scores may be advantageous in influencing performance in attack thus ensuring success in competition in volleyball.

THE INFLUENCE OF FATIGUE ON COGNITIVE REACTIONS IN YOUNG BASKETBALL PLAYERS.

MIKOLAJEC, K., LITKOWYCZ, R., GRYKO, K.

ACADEMY OF PHYSICAL EDUCATION

INTRODUCTION:Considering the level of performance in basketball it is important to know the impact of fatigue on player's cognitive reactions both during the effort as well as the restitution phase. It is essential for the athlete to be in the psycho-physical comfort zone, which means not reveal any signs of circular (muscular) or central (nervous) dis-function or any homeostatic disturbances (Chmura et. al. 2002, Mroczek et. al. 2011). So far not all mechanisms responsible for the intensification of the fatigue process in certain sport disciplines have been identified, especially when it is related to young athletes. However, the negative influence of that factor on basketball player's outcomes, like turnovers, missed shots, delayed defensive reaction and the other errors are quite obvious. Therefore the goal of this study was to investigate the relationship between the level of endurance and cognitive reactions time in young basketball players.
METHODS: 15 well-trained young basketball players (aged 17-18 years) participated in the study. Athletes were practicing 4 times per week and playing one game in the junior league. The endurance level has been determined using the Wingate test (MONARK cycloergometer). The anaerobic threshold and the maximal oxygen uptake were made during the progressive test (the intensity increases of 30W each 3 minutes). Basketball player's psychomotor capability (speed of reactions to visual and auditory stimuli) has also been evaluated before and after effort as well as during restitution phase. The above-mentioned conditions facilitated the determination of arterial blood gas parameters, lactate concentration as well as the acid-base homeostasis.
RESULTS: The basketball players maintained the reaction time on the same level, however the number of errors increased during first restitution phase (1-5'). Considering the second restitution period (6'-15') an improvement of the choice-related reactions and the decrease of simple reactions time was recorded. An analysis of the relationships between anaerobic power variables and the post-exercise reaction time aspects revealed significant correlation between the average, minimal, maximum reaction time and relative, maximum power as well as the total work.
CONCLUSION: The analysis of basketball players' cognitive reactions has revealed that directly after intensive physical activity first phase of restitution process is activated by the quick phase - during which the haemoglobin and myoglobin restoration as well as the phosphocreatine and ATP re-synthesis taking place allowing to maintain an optimal level of reaction time. The activation of the antioxidant system will have a positive influence especially on the accuracy of reactions in the second phase of restitution (6-15'). The efficiency of cortical centres responsible for the analytical and decision-making process were enhanced in that phase of restitution.

THE EFFECT OF THE TRANSITION PERIOD ON THE ANTHROPOMETRIC AND PERFORMANCE PARAMETERS IN ELITE FEMALE SOCCER PLAYERS.

PARPA, K., MICHAELIDES, M.

UCLAN UNIVERSITY OF CYPRUS

INTRODUCTION:The transition period has been demonstrated to result in moderate negative changes in body composition, sprint performance as well as muscle power. Furthermore, decrements were reported in maximal oxygen consumption, time to exhaustion and intermittent running performance. The purpose of this study was to examine the effect of the transition period on the anthropometric and performance parameters in elite female soccer players.
METHODS: Eighteen female elite soccer players (age 23.61 +/- 4.29 years) participated in this study.
RESULTS: The cardiopulmonary exercise testing revealed significant ($p<0.01$) reductions in Vo2 max and running time on the treadmill when the players were tested following the transition period. Significant reductions ($p<0.01$) were also demonstrated in quadriceps strength at 60 degrees/sec. Last but not least, the transition period resulted in significant ($p<0.01$) increases in body weight and body fat.
CONCLUSION: The transition period has been demonstrated to negatively affect anthropometric and performance parameters in female soccer players. Off-season programs should be tailored towards maintaining players' strength as well as endurance in order to prevent possible injuries during the demanding pre-season period. Players should be provided with appropriate training regimens that can help them not only maintain their fitness levels but also recover and rest before the pre-season training period.

COMPARATIVE ANALYTICAL STUDY OF THE APPROACH STAGE TO PERFORM THE SPIKE SKILL OF THE VOLLEYBALL GAME AND ITS RELATIONSHIP TO ACCURACY

QADIR, N., DARWEESH, N., JALAL, N.

KOYA UNIVERSITY

INTRODUCTION:The spike skill comes with more accurate results as the jump is faster, higher, and more convenient. These results can not be obtained unless the player adjusts the starting and preparing steps to jump. The kinetic momentum obtained by the player as a result of the starting moves is equal to the motion of the player according to the law (kinetic momentum = pushed). As we see during game section of the players perform the skill of spike one step and then jump and there are players performed by two or three steps by distance and height of the ball. the biomechanics literature has shown that the hitter will use the approach to achieve a high jump with minimal horizontal motion the 'backswing' or 'preparatory' phase and the 'forward swing' or 'hitting' phase (1).
METHODS: (N=10) Players represent Koya University Volleyball team, for the academic year 2017-2018. The research sample represents (83.33%) of the research community, for homogeneity. Researcher used the coefficient of variation of the physical variables, ranging between (2.6 - 8.8%). Each player has played for at least four years, and all the players use their right hand. The average age of the sample was 22.70 years, body mass 69.80 kg, body height 185.40 cm.
RESULTS: By applying the variance analysis law to compare the steps of the approach phase to the volleyball skill, the result was as follows (12.175,10.292,10.937,6,294) with probability values (P <0.000). There were generally significant differences between skill performance in one step, two steps and three steps when using the (Scheffe) equation. by going back to the computational medium to find out the difference in favor of any step of approach the results showed that the variables (speed of starting and power) during the performance of the skill in three steps was greater by a mean value (3.331) (7787.0120) respectively. There was also a strong relationship of the biomechanical variables between them in general, whether the performance of the skill in one step or two steps or three steps.
CONCLUSION: In the performance of the skill of spike the player must take a good preparatory situation that the approach stage is not less than two steps. The exercise must be performed in accordance with the skill technique of body weight against gravity in volleyball. Variables (movement time, starting speed and Jumping distance) during the performance of the spike skill have a strong relationship to the explosive power of the legs in of volleyball player.

COMBINED PASSIVE AND ACTIVE HEAT EXPOSURE TO ENHANCE RUNNING PERFORMANCE IN WINTER-BASED TEAM SPORTS

PYNE, D., GALE, R., ETXEBARRIA, N., PUMPA, K.

UNIVERSITY OF CANBERRA

INTRODUCTION:Studies of heat acclimation have typically employed consecutive 7-14 day exposures in individual sports (mode-specific cycling and running) to elicit thermal adaptations and improvements in performance (1). However these interventions are more difficult to implement in team sports given a large number of players and a multitude of skills, conditioning and gym-based sessions. We investigated the effects of non-consecutive day heat training combining high-intensity interval cycling with passive heat exposure to enhance mid-season running performance in team sport (football) players.
METHODS: Thirty club-level male Australian Rules Football players were randomly assigned to either Passive + Active Heat (n=10), Active Heat (AH; n=10) or Control (CON; n=10) experimental groups and completed 6 laboratory-based training sessions over a 12 day period (each session comprising 6 x (5 x 10 sec) high-intensity sprints on a cycling ergometer) in either 35°C, 50% relative humidity (RH) or 18°C, 50% RH. The players in PAH were exposed passively to heat (35°C, 50%) for 20 min prior to commencing exercise. Thermal adaptation was assessed via a submaximal heat stress test performed on a treadmill, followed by a time-to-exhaustion treadmill test in 35°C and 50% RH to assess running performance.
RESULTS: Running time-to-exhaustion increased by 26 ± 8% in PAH (0.88, ±0.23; standardised mean, ±90% confidence limits), 29 ± 12% in AH (1.23, ±0.45) and 10 ± 11% in CON (0.45, ±0.48) compared with baseline. Both PAH (0.52, ±0.42) and AH (0.35, ±0.57) heat training yielded substantially greater improvements in running performance than the control group. Physiological and perceptual measures were largely unchanged between baseline and post-intervention heat stress tests within and between the three conditions.
CONCLUSION: Where thermal adaptation is not a priority, a short-term high-intensity cycling protocol in hot conditions may be an effective means of inducing small improvements in running performance in team sport players mid-season. A short period of heat exposure before heat training appears to be of little additional benefit. This protocol should promote fitness improvements while minimising lower limb load for field- or court-based team sport players.

KINEMATIC CHARACTERISTICS OF TWO TYPES OF INSTEP KICKING IN FEMALE SOCCER PLAYERS

SAKAMOTO, K.

CENTER FOR LIBERAL ARTS

INTRODUCTION:Several studies reported that trained female and male players have different techniques (1). However, the comparison between gender differences and the investigation on among female players are insufficient. The purpose of this study was to investigate the characteristics of female player's kicking by focusing on the support leg, pelvis and trunk motion, and obtained the kicking technique to increase ball velocity to give feedback to female players.
METHODS: The participants were eight female athletes specializing in soccer at a university with a department of physical education (height: 160.4 ± 4.9 cm; weight 57.1 ± 5.7 kg in weight). After adequate warm up, all participants were instructed to perform maximal instep kicks towards a goal 10 m away, using the dominant leg. Imaging was performed using 10 infrared cameras (Vicon Motion Systems, Oxford, UK); three-dimensional coordinate data for each body part (16 anthropometric points with reflective markers attached) during the kicking motion were collected at 250 Hz. The stationary coordinate system was defined as a right-handed system in which the x-axis is the direction orthogonal to the horizontal kicking direction at the start of the task, the y-axis is the horizontal kick direction at the start of the task, and the z-axis is the vertical direction. The data, including the extrapolated points, were smoothed using a fourth-order phase-shift-free Butterworth digital filter to determine the optimum cut-off frequency (20 Hz) (Winter, 2004). The period from touch-down of the support leg to ball impact (Forward swing phase) was normalized to 100%.

RESULTS: As a result, two different techniques were observed in female kicking. Four female players naturally follow through with a jump (Lifted kicking), whereas another four female players avoid this after impact (Normal kicking). Therefore, the participants divided into two groups and compared their motion respectively.
CONCLUSION: The lifted kicking motion was affected slightly by knee flexion and ankle dorsi-flexion ($p < 0.05$). In addition, the pelvis obliquity of lifted kicking was larger than that of non-lifted kicking resulting in the greater trunk back lean ($p < 0.05$). Medial obliquity of lifted kicking might have occurred naturally to gain higher vertical hip velocity (≒ foot velocity (2)). On the other hand, Non-lifted kicking might generated swing velocity by keeping lateral obliquity and obtaining large pelvis posterior during the forward swing. The range of motion between trunk and pelvis (twist angle) of lifted kicking was larger than that of non-lifted kicking ($p < 0.05$). This generate larger twist would make the difference in the foot velocity between lifted and non-lifted kicking.
The findings suggest that female players might be able to have two kicking techniques by conscious intervention.

JUDGES' EVALUATION RELIABILITY AMONG VISUALIZING TOOLS IN HIP-HOP DANCE

SATO, N., HOPPER, L.S.

NAGOYA GAKUIN UNIVERSITY

INTRODUCTION:The evaluation of hip-hop dance performance depends on the subjective impression of judges. Judges' evaluations are likely to be affected by a dancer's motion, clothes, facial attractiveness, physical features and shapes. In order to extract the motion characteristics which judges use to evaluate hip-hop dance, a reliable visualizing tool which excludes the information other than the motion is needed. The purpose of this study was to determine the reliability visualizing tool in the evaluation of hip-hop dance movement.
METHODS: Five expert hip-hop dancers and five non-expert hip-hop dancers participated in this study. The dancers were asked to perform 10 cycles of a basic rhythmic hip-hop movement. Dancer movements were captured using an eight-camera motion capture system and two video cameras. A stick figure animation was also created in a motion capture software. A humanoid animation was created as reported in Hopper et al.1 Seven judges evaluated the dancers' performance by observing the actual video, the stick figure animation, and the humanoid animation on a computer display. In each observation method, the judges evaluated 20 dance trials and they are not informed that they repeated an evaluation. The judges graded each performance on a scale of 1-10, with 10 being the highest grade. The judges' scores were converted into T-scores to standardise their scores. The reliability of the evaluations were examined using inter- and intra-class correlation coefficients.
RESULTS: The video was the highest method in the intra-class correlation coefficient (ICC = 0.875). However, there was little difference between the video and the humanoid animation (ICC = 0.872). The stick figure animation was the lowest method (ICC = 0.795). The inter-class correlation coefficient for the judges' evaluations of the humanoid animation demonstrated the highest reliability among three methods (ICC = 0.925).
CONCLUSION: Evaluation of the humanoid animation could minimize the judges' bias compared to the video and stick figure animation evaluations. The humanoid animation appears to be a reliable method for the evaluation of hip-hop dance movement.

MAXIMAL AND SUB-MAXIMAL RUNNING PERFORMANCE IN JAPANESE COLLEGIATE ENDURANCE ATHLETES

KUMAGAWA, D., UEHARA, K., IMAWAKA, T., HIRATSUKA, K., TSUNODA, N.

KOKUSHIKAN UNIVERSITY

INTRODUCTION:In order to improve athletic performance, it is essential to investigate the exercise intensity of each type of competition and to suggest an appropriate training intensity according to the physical fitness level of individual athletes. it is necessary to use physiological indicators to regularly examine athletes whose physical fitness levels change dramatically throughout the year. It is especially important to suggest an appropriate training intensity for running because winter-sports athletes cannot recreate their competitive environment in other seasons, and often train on dry land in the summer. This study therefore evaluated the maximal and sub-maximal running performance of summer- and winter-sports endurance athletes.
METHODS: Participants were 29 male Japanese collegiate athletes (400-m runners, 800-m runners, long-distance runners, and cross-country skiers). Their maximal and sub-maximal running performance was evaluated by incremental running tests, which consisted of a variable number of 3-min runs on a treadmill with 1-min rest periods between runs. Oxygen consumption (VO2), blood lactate concentration, heart rate (HR), and rating of perceived exertion (RPE) were continuously measured. Running velocities and HR at blood lactate concentrations of 2 mmol and 4 mmol (V@2 mM and V@4 mM, and HR@2 mM and HR@4 mM, respectively) were calculated.
RESULTS: The VO2max normalized by body mass was significantly higher in long-distance runners than in 400-m runners, 800-m runners, and cross-country skiers. No significant differences were found between cross-country skiers and 400-m or 800-m runners. The V@2 mM and V@4 mM observed in long-distance runners were significantly higher than those observed in the other three groups. These values were found to be significantly higher in cross-country skiers than in 400-m or 800-m runners. However, no significant differences in HR@2 mM and HR@4 mM were found among the groups for all event types.
CONCLUSION: These results show that long-distance runners are superior in both maximal and sub-maximal running performance. In addition, we found that the running capacity of the cross-country skiers was nearly the same as that of the mid-distance runners. However, with respect to sub-maximal running performance, high running velocities were possible in cross-country skiers despite having the same heart rate.

CHANGES IN THE VERTICAL JUMP BILATERAL DEFICIT FOLLOWING SHORT-TERM UNILATERAL VS. BILATERAL PLYOMETRIC TRAINING

BOGDANIS, G.C.1, KALOHERI, O.1, TSOUKOS, A.1, VELIGEKAS, P.1, TERZIS, G.1, BROWN, L.E.2

<1> NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, GREECE; <2> CALIFORNIA STATE UNIVERSITY, FULLERTON, USA

INTRODUCTION:Countermovement jump (CMJ) height in double leg jumping may be lower than the sum of right and left leg heights, a phenomenon called the bilateral deficit (1). Based on this evidence, it was hypothesized that single leg, i.e. unilateral training (U) may allow greater loading and induce greater improvements in lower limb muscle power, compared with an equal volume of two-leg, i.e. bilateral) training (B). Therefore, the purpose of this study was to examine the effects of 6 weeks of U vs. B plyometric training on the CMJ bilateral deficit.

METHODS: Fifteen moderately trained university students (8 males (age: 19.8±2.9 years, height: 1.78±0.06 m, body mass: 72.3±10.2 kg) and 7 females (age: 19.4±0.5 years, height: 1.64±0.07 m, body mass: 58.0±4.1 kg) were matched for baseline CMJ performance and then randomly assigned to either the U (n=7) or the B (n=8) training group. Participants performed 2 sessions per week of maximal effort plyometric leg exercises for 6 weeks. Each session included 6 exercises (3 sets x 10 repetitions). Total exercise volume was the same in both groups, with the B group performing all exercises with both legs, while the U group performed half the repetitions with each leg. Jumping performance was assessed by double and single leg CMJ while the bilateral deficit index (BI%) was calculated as: (100 x (two-leg jump height/ right+left leg jump height)) - 100. Results were analyzed using a 2 x 2 (time x group) ANOVA with repeated measures and Tukey's post-hoc follow-up.
RESULTS: There was a significant time x group interaction for BI% (p=0.002). At baseline, BI% was not different from zero, indicating neither facilitation nor deficit in both groups (B: -0.4±12.7%, U: 0.9±7.2%). After training, BI% was increased in the B group to 6.8±11.5% (p=0.045), while for the U group, BI% showed a non-significant decrease to -5.0±6.5% (p=0.14). Double-leg CMJ height improved similarly in the U and B group, by 12% (p<0.001). However unilateral improved only in the U group (19.0±7.1%, p<0.001) and remained unchanged in the B group (3.4±8.4%, p=0.80).
CONCLUSION: The results of the present study demonstrate that B training results in bilateral facilitation, with two-leg CMJ height being greater than the sum of the right + left leg CMJ height. The unchanged BI% in the U group after training shows that unilateral plyometric training may be more effective than an equal volume of bilateral training, since it increases both single and double leg CMJ performance.

RELATIONSHIP OF VERTICAL JUMPING AND LEG LENGTH-NORMALIZED AGILITY T-TEST IN COLLEGIATE COMBAT ATHLETES

XU, K.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION:Agility is an important physical attribute for successful participation in combat athletes. Power production is believed to be an important factor in agility (1). Although there are numerous studies revealing the relationship of power and agility in team sport events, the power-based agility performance is still uncertain in combat athletes. Anthropometrics were not strongly related to agility performance, however, leg length is found to be negatively associated with performance in agility (2). The purpose of this study was to determine the relationship between the performance of vertical jump and leg length-normalized agility T-test to evaluate the influence of power on agility in collegiate combat athletes.
METHODS: A total of 28 collegiate male combat athletes (10 taekwondo athletes, 10 wrestlers, 8 boxers) participated in this investigation. Participant's leg length was measured from the anterior superior iliac spine to the distal tip of the medial malleolus of dominant limb. The participants performed a vertical jump test for 3 times to measure the flight time, height, and impulse. Thirty minutes after the last vertical jump, the participants performed a modified agility T-test with the running distance normalized to leg length (1 m running distance/10 cm leg length). Agility T-test was measured in 4 parameters: time of forward running (F time), time of shuffle steps (S time), time of backward running (B time), and total running time (T time).
RESULTS: No significant difference was found between groups in F time, S time, B time, and T time of agility T-test, as well as flight time, height, and impulse in vertical jump. Moderate correlations between flight time and height with S time (r = -0.451 and r = -0.419, respectively) as well as T time (r = -0.405 and r = -0.434, respectively) were observed. Moderate-to-strong correlations between impulse with S time and T time (r = -0.591 and r = -0.608, respectively) were found.
CONCLUSION: Moderate to strong relationships exist between power and leg length-normalized agility T-test attributes in collegiate combat athletes. Improved testing of power-related attributes should enable combat athletes to develop targeted training plans for enhancing their performance.

EFFECTIVENESS OF POLARIZED VERSUS THRESHOLD TRAINING ON NEUROMUSCULAR VARIABLES IN ULTRARUNNERS

PÉREZ-HERNÁNDEZ, A., RAMOS-CAMPO, D., RUBIO-ARIAS, J.A., MARÍN-PAGÁN, C., CARLOS-VIVAS, J., FREITAS, T.T., MARTÍNEZ-NOGUERA, F.J., ORTELANO, R., MARÍN-CASCALES, E., CHUNG, L.H., ALCARAZ, P.E.

SPORT SCIENCE FACULTY. CATHOLIC UNIVERSITY OF MURCIA, MURCIA, SPAIN

INTRODUCTION:In recent years, there has been a growing interest in ultra-marathon races with an associated increase in the number of competitions, participants and research1. The factors that determine performance are large but most are related to the physiological profile, such as: running economy, VO2max, ventilatory thresholds (VT)2, levels of strength4. There are different models that distribute the intensity levels differently during periodization that can be more or less effective for ultrarunners9. Most studies have focused only on the effect of different intensity distributions on parameters of aerobic performance. Also, despite the importance of strength in endurance, it is unknown how the different models of intensity distribution can affect neuromuscular adaptations in ultrarunners. Therefore, the aim of this study was to compare the effect of two training programs (similar load and volume) with different intensity distribution (polarized vs threshold) in neuromuscular variables in recreational ultrarunners.
METHODS: Twenty recreationally ultrarunners were allocated to POL (n=11; age: 40.6 • 9.7 years;; weight: 73.5 • 10.8 kg; VO2max: 55.8 • 4.9 ml/kg/min) or THR group (n=9; age: 36.8 • 9.2 years; weight: 75.5 • 10.4 kg;VO2max: 57.1 • 5.2 ml/kg/min) and performed the 12 weeks of training program. Both programs had similar total time and load but a different intensity distribution. Training intensity was divided on 3 different zones which are determined by ventilatory threshold 1 (VT1) and 2 (VT2): Zone 1: Heart Rate (HR) < VT1; Zone 2: HR between VT1-VT2; Zone 3: HR > VT2. After training distribution were to POL (79.8 • 2.1% in Zone 1; 3.9 • 1.9% in Zone 2; 16.4 • 1.5% in Zone 3) and THR (67.2 • 4.6% in Zone 1; 33.8 • 4.6% in Zone 2; 0% in Zone 3). Participants of both groups performed 5 running sessions, 2 strength sessions and one day of total rest per week. In this way, THR group performed 3 sessions in zone 2 and 2 sessions in zone 1 per week. The POL group, performed 2 high intensity sessions (zone 3)and 3 sessions of low intensity (zone 1) per week. Strength training was the same for both groups. Rate of force development (RFD) and EMG were measured before and after each program.
RESULTS: The results of the effects on RFD before and after the training program showed no significant differences in any variable in THR group. However, after training, a significant decrease in RFD 0-200 (N·s-1) (Δ- 11,7; p= < 0.001; ES = 1.40) and RFD PEAK (N·s-1) (Δ- 18 %; p= < 0.001; ES = 1.40) were observed in POL group.In THR group, there was a significant increase in mean EMG amplitude (Δ-24.4%;p=0.02; ES=1.4). However, there were no significant differences in peak EMG amplitude between groups before or after the training program.
CONCLUSION: Similar adaptations in neuromuscular performance can be achieved after 12-week of POL or THR intensity distribution. However, THR distribution appears to better maintain strength (RFD) values and improved mean EMG amplitude

PREDICTIVE VALUE OF LEG LENGTH-NORMALIZED AGILITY T-TEST IN COLLEGIATE COMBAT ATHLETES

WANG, I.H., CHANG, Y.R., ZHOU, T.R., LIU, Y.C., CHOU, K.M., WANG, D.C.
NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION:Agility is the ability to maintain a controlled body position and rapidly change direction, which has been defined as balance, coordination, power, and speed components (1). Anthropometrics were not strongly related to agility performance, however, leg length is found to be negatively associated with performance in agility (2). Agility T-test has been used to assess agility in athletes and nonathletes, but the sensitivity of this test has not been established. This study aimed to examine the sensitivity of leg length-normalized agility T-test to assess the performance-based training effect in collegiate combat athletes.
METHODS: A total of 38 college students and combat athletes (10 nonathletes, 10 taekwondo athletes, 10 wrestlers, 8 boxers) participated in this investigation. Participant's leg length was measured from the anterior superior iliac spine to the distal tip of the medial malleolus of dominant limb. The participants performed 3 repetitions of the standard agility T-test (10 m x 10 m) with 3 min rest interval between each running. After 5 min rest interval, the participants performed a modified agility T-test with the running distance normalized to leg length (1 m running distance/10 cm leg length). Agility T-test was measured in 4 parameters: time of forward running (F time), time of shuffle steps (S time), time of backward running (B time), and total running time (T time).
RESULTS: No significant difference was found between groups in F time, S time, B time, and T time of standard agility T-test. However, in the leg length-normalized agility T-test, there were significant differences between groups in all parameters. Boxers showed less F time compared to nonathletes ($p<0.05$). Wrestlers and taekwondo athletes showed less S time as well as B time compared to nonathletes ($p<0.05$ in each comparison). Combat athletes showed less T time compared to nonathletes (wrestlers and boxers vs nonathletes, $p<0.05$; taekwondo athletes vs nonathletes, $p<0.01$). There was no significant difference between combat athletes in 4 parameters of leg length-normalized agility T-test.
CONCLUSION: The leg length-normalized agility T-test might be considered as a sensitive test to evaluate specific agility of combat athletes. The development of an anthropometric normalized agility T-test can serve as a diagnostic criterion in predicting combat athlete performance.

EXAMINATION OF DECISION-MAKING SKILLS BETWEEN PROFESSIONALS

LAKI, A., KÉRI, P., KOSZOGOVITS, M., NAGYVARADI, K., IHÁSZ, F., SZABÓ, A.
EÖTVÖS LORÁND TUDOMÁNYEGYETEM ELTE

INTRODUCTION:Ball games and the combat sports belong to opened skill sports. Constant aerobic work during the game is specific to these sports, together with short, intense periodic pressure, which energy demand reach to the anaerobic range. Basketball players and combat sport players are under constantly decision-making pressure, they have to make decisions during the game both in the aerobic and anaerobic zone. Athletics is a closed skill sport, sprinters perform their distance mainly in the anaerobic range and they do not have to make decisions.
METHODS: We analysed 38 professional sportmen (11 basketball players, 8 kickbox players, 19 athletes), the average age is 21±3,8. The body consistence was measured with „InBody 720" equipment which operate with bioimpedancy. The characteristics of the cardiorespiratoric system was examined with H/P Cosmos LE200CE equipment (DE 83365 Nussdorf-Traunstein Germany) we measured it till the anaerobic threshold. The rest pulse (Po), (beat·min–1), and maximal pulse (Pmax), (beat·min–1), the ventillation VE (BTPS l·min–1) and its components was measured with Master Screen CPX 50/60 Hz equipment (CareFusion Germany 234 GmbH 97204 Hoechberg)
We analyzed their decision-making skills in different pressure ranges in the context of the metabolical background with WinPsycho 2000 (Colour perception, Speed perception) psychological tests, laptop projector (Epson LCD projector, H719B, 3-5, Owa 3 chome, Suwa-shi, Nagano-ken 392-8502 Japan) and Hama Gaming Mouse „uRage Unleashed WL" (Hama GmbH & Co KG D-86652 Monheim)
RESULTS: At the presentation of the results we concentrate on the reaction time and mistakes of the psychological test, as well as the correlations with the physical pressure. We have kept a special attention on the personal differences and the sports specifications. We have found significant differences on different stages of the pressure in point of the reaction time and failure rate. A significant improvement ($p<0,05$) can be seen by the colour perception mistakes between the average of the rest test (1,7±2) and the average of the anaerobic range (0,8±0,9).
CONCLUSION: The decision-making ability of the sportmen depends on the physical pressure, significant personal differences can be seen between the aerobic and anaerobic work. We would like to analyse more decision-making ability by other opened and closed skill sport professionals in the future.

ANTHROPOMETRIC AND BODY COMPOSITION OF THE WOMEN'S NATIONAL TEAM AND OF THE U15 ELITE PLAYERS IN HANDBALL

TRÓZNAI, ZS., PÁPAI, J., UTCZÁS, K., NÉGELE, Z., NYAKAS, C., JUHÁSZ, I., SZABÓ, T., PETRIDIS, L.
UNIVERSITY OF PHYSICAL EDUCATION

INTRODUCTION:Body structure and somatotype characteristics of elite athletes in a given sport is an important aspect in talent identification and in the selection process of young athletes. The purpose of our study was to compare the body structure of elite female adolescent players (U15) with the body structure of the Hungarian womens national handball team.
METHODS: The analysis included 60 elite adolescent players (U15) and 34 players from the womens national handball team. Elite U15 players were selected through a multilevel selection process organized by the Handball Federation, and which involved all competitive handball teams in Hungary. Body measurements were taken on the basis of Martin technique (Martin & Saller, 1957). Anthropometric somatotype was determined by the Heath–Carter method (1975 and 1980) using the regression equations of Szmodis (1977). The dispersion of the somatoplots was estimated by using the SDM indicator (Ross et al., 1977; Bodzsár & Zsákai, 2004). Body composition was determined by bioelectrical impedance analysis (InBody720). Differences between the two groups were examined with t-test and one-way ANOVA was used to assess differences between different playing positions.
RESULTS: In most cases anthropometric measurements of U15 handball players were much lower than that of the women's team, while mean skinfold values did not differ between the two groups. The absolute and relative mass of musculo-skeletal system was notably larger in the women's team. Players of the national team had more mesomorph, and less ectomorph physique, than their younger

counterparts. In both groups distinct profiles existed for different playing positions based mainly on the longitudinal-, width- and skinfold measurements. The average somatoplots were situated in different areas of the somatochart. Larger distances between the adult players referred to a more position specific body shape. The goalkeepers and wings proved to be the most homogeneous subgroups in both adolescent and adult groups.
CONCLUSION: The results for body size and shape of elite adult and U15 handball players indicate that in late puberty the body structure of young athletes was far from the „gold standard" as this was represented by the women's national team. Significant changes are still expected during adolescence in order to reach the typical body build characteristics in handball. The changes include particularly the body composition, which depends on both genetic factors and on training adaptation. In the selection process those young players, whose body build approaches the typical body build for a given playing position will have higher chances to be selected.

STUDY OF THE PREDICTIVE POWER OF TWO LABORATORY EXERCISE TESTS FOR SHORT TRAIL RUNNING PERFORMANCE

HODY, S., RODRIGUEZ DE LA CRUZ, C., DINVERNO, B., BURY, T.

UNIVERSITY OF LIEGE

INTRODUCTION:Trail running (TR), a new endurance discipline with distinct physiological demands, has gained popularity in the recent years. However, only few studies have looked at exercise testing strategies to predict short TR performance. Therefore, the aim of this study was to examine the predictive power of the physiological variables obtained from two different treadmill running tests.
METHODS: Eight competitive male trail runners (24 ± 6years; 74.7 ± 6.5kg; 14.6 ± 5.1% body fat) completed a level and uphill treadmill laboratory tests followed by a 31km trail race (900m positive declivity). Both laboratory tests were performed in a randomized order with a 7-12days interval period. They consisted of a 5-minute warmup stage of level running (0%, 8km.h-1) followed by 3-minute graded steps until exhaustion (level protocol: 0%, increase 2km.h-1 until 14km.h-1 followed by 1km/h increase; uphill protocol: +10%, increase 1km.h-1). Gas exchanges, heart rate (HR) and capillary blood lactate were measured for determination of maximal oxygen uptake (VO2max), maximal aerobic speed (MAS) and lactate thresholds (LT). The measured physiological variables were correlated to the trail finishing race time, evaluating their predictive power.
RESULTS: Comparison between the physiological parameters determined by level and uphill protocols revealed significative differences in VO2max and MAS (level: 48.5 ± 5.1 ml.min-1.kg-1 and 15.8 ± 1.1 km.h-1; uphill: 51.5 ± 4.6 ml.min-1.kg-1 and 10.3 ± 0.8 km.h -1; $p<0.05$). VO2max and MAS determined in uphill condition showed a stronger correlation (r=0.93) compared to those obtained in level condition (r=0.57).
The correlation analysis between the physiological parameters and the race time revealed no significative data. However, it is of interest to underlie that VO2max appeared more predictive of the race time when determined in uphill condition (r=-0.523) than in level condition (r=-0.167).
CONCLUSION: Our study tend to suggest that the uphill running test would be better in predicting trail races than the level running test. Further investigations with larger population including more variables that may impact on trail performance (such as muscle function) should be conducted.

ANTHROPOMETRY AND HEART RATE INFLUENCE ON SWIMMING PERFORMANCE OF ADOLESCENT ATHLETES OF WATER SPORTS

ALMÁSI, G.1, BOSNYÁK, E.1, FARKAS, A.1, MÓRA, Á.2, TÓTH, M.1, SZMODIS, M.1

1 UNIVERSITY OF PHYSICAL EDUCATION, 2 UNIVERSITY OF PÉCS

INTRODUCTION:Water sports are one of the most famous segments of sports. Hungarian athletes are known to be successful in these events, but to maintain this level of performance, adequate selection methods are irreplaceable. With our research we would like to take part in the creation of a new selecting method based on scientific researches and findings. In our study we focused on water sports (swimming - S and water polo - W). We believe that there is/are certain anthropometric or physiological factor, that influence the athlete's performance.
METHODS: Our research contained adolescent athletes, between 11-18 years old (N=70 people, girls n=30, boys n=46 13.99±4.43 yrs). We created groups depending on age, gender (younger male (YM), older male (OM), younger female (YF) older female (OF)) and sport events. Anthropometric measurements were based on the recommendation of the International Biological Program (1). Our field test contained a warm up session on different energy levels followed by a maximal intensity exercise (200 freestyle swimming). Heart rate was monitored during the whole procedure to define maximal heart rate (HRmax) and during the rest phases first 60 seconds (R60) after the 200 freestyle swimming with polar V800 heart rate monitor. We used standard statistic procedures to analyse the acquired data (paired t-test and correlation analyses) where we accepted the results significant with $p<0,05$ value.
RESULTS: Besides the evident differences between gender and age groups, we found several, significant results: Comparing OM S (14.81±1.95 yrs) to OM W (15.74±0.96 yrs), we found, that OM S had lower fat percentage (14.93±2.03% vs. 17.97±4.08%), lower BMI (20.01±2.37 kg/m2 vs. 22.44±2.92 kg/m2), lower plastic index (80.78±5.61 cm vs. 88.91±2.92 cm), lower endomorphic index (2.05±0.48 vs. 2.82±1.01), higher bone percentage (17.97±2.13% vs. 16.40±1.73%), and higher swimming speed (1.47±0.13 m/s vs. 1.30±0.08 m/s) than OM W. Between OF S (14.04±1.05 yrs) and OF W (14.91±0.61 yrs) we experienced difference in swimming speed (1.38±0.09 m/s vs. 1.26±0.08 m/s). Using of correlation analysis we found the following, significant connections: OM's (16.88±0.85 yrs) swimming was partially correlated with R60 (r2=0.49) and by HRmax/R60 ratio (r2=0.695). OF's (14.98±0.74 yrs) swimming speed correlated with HRmax (r2=0.543). OM W's speed correlated with hand circumference (r2=0.66) chest width (r2=0.61) chest circumference (r2=0.586).
CONCLUSION: We found remarkable differences comparing athletes by sport event and correlation between the body dimensions, heart rate and swimming performance. Our further goal is to conduct repeated measures on the same athletes, creating a longitudinal study focusing on the determinative factors, so we can create a selecting method with higher accuracy for water sports.

LONGITUDINAL STUDY ON PHYSIQUE AND MOTOR ABILITY AND CONDITIONING SUPPORT OF FEMALE COLLEGIATE BADMINTON PLAYERS IN JAPAN

WATANABE, E.1, MISHIMA, T.2, AIZAWA, K.1, ABUTANI, H.3, SATO, T.4, MIYAZAKI, M.5, SEKI, K.5

<1> SENSHU UNIVERSITY, INSTITUTE OF SPORT, <2> OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES,, <3> SMART SYSTÉM STRENGTH, <4> JISSEN WOMEN'S UNIVERSITY, <5> WASEDA UNIVERSITY

INTRODUCTION:Badminton is one of the popular sports enjoyed widely. Many young athletes are doing hard training to participate in the Olympic Games because the Tokyo Olympics are held in 2020. In order to win in the game, it is necessary to prepare for motor ability, skill and mind. We are doing research aiming at the way of training to match the healthy growth and development of each player and the prevention of sports disorder through sports life. In this study, we aimed to clarify the physique and motor ability, and confirm a change of the condition for female collegiate badminton players.
METHODS: Subjects were female collegiate badminton players who belong to the badminton club. The period of this study started from 2010 and it was up to 2018. The total of 141 players participated in this study. We classified the grade and competition level A or B. Group A is the player who participated in an all-Japan badminton championship (the most authoritative domestic meeting). Group B will be other players. We performed body-based measurement (height, weight, %body fat) and motor ability test (20m dash, pro-agility test, standing long jump, side steps, vertical jump, rebound jump index). We carried out the measurement once a year. And we performed the condition measurement of the players from March 2015. We used blood hemoglobin estimate index of the condition and measured once a month.
RESULTS: There was no difference between the groups in the first and second year. In the third year, the tendency was seen in side steps and rebound jump index (p=.068, =.099). In the fourth year, the tendency was seen in standing long jump, vertical jump and rebound jump index (p=.046, =.089, =.052). As a result of the condition evaluation, there was a difference in May 2015, December 2015, May 2016, May 2017 (P=.023, .062, .009, .060, A>B). The coefficient of variation was also larger in group B (A=0.10, B=0.18). In addition, there are many players who show anemia tendency from December to April every year regardless of group (<11g/dL).
CONCLUSION: From the results, differences in motor ability between A and B in the third year are considered to show the results of steady training of three years. It seems that the improvement of instantaneous power is strongly influential as an important factor for female badminton players ability to improve their competitiveness. Since there were many players with anemia tendency regardless of the competition level, it is desirable to provide medical science information such as nutrition and collegiate lifestyle necessary for players.
A longitudinal study with players of different ages is necessary to complement this study, and measurement is still continuing now.

EFFECTS OF HYPEROXIA DURING RECOVERY FROM 3 × 3-MIN BOUTS IN SKIERS PERFORMANCE

POLÍVKOVÁ, J., SCHÜTZOVÁ, S., SUCHÝ, J.

CHARLES UNIVERSITY, FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION:Many studies report that inhalation of hyperoxic gas mixtures during recovery has an effect on subsequent, immediate sports performance lasting up to two minutes (Haseler, Hogan, & Richardson, 1999; Nummela, Hamalainen, & Rusko, 2002; Sperlich et al., 2011). In this study, we monitored the effect of continuous inhalation of concentrated oxygen on performance during repeated exertion on the ski simulator, while resting between these exertions. The study was supported by the Charles University, project GA UK No. 62418 and by the PROGRESS Q41 program.
METHODS: Test subjects (n = 10) underwent two batteries of tests, each of which included three series of 3-minute exertions on a ski simulator with a 3-minute rest between individual exertions. The test battery simulated the load in the youngest cross-country skiing discipline – team sprint. Throughout the rest period, a randomized part of the test subjects inhaled a hyperoxic mixture and the second part of the test subjects inhaled the placebo. The source of the hyperoxic mixture with an oxygen concentration of 93% +3.5% / -3% was the AirSep® NewLife® Intensity oxygen concentrator supplemented with a polyethylene reservoir to which a breathing mask was attached via a two-way valve. The placebo was administered in the same way (reservoir, mask), but the air source was a compressor unit. To verify the set targets, mechanical performance on the ski simulator was measured, and a blood sample was taken, always right before the exertion and immediately after it, to determine the blood lactate level.
RESULTS: No statistically significant difference in performance was demonstrated between subjects inhaling the hyperoxic mixture and those inhaling the placebo ($p \geq 0.075$; $d \leq 0.194$). Likewise, no statistically significant difference was observed in the blood lactate concentration ($p \geq 0.327$; $d \leq 0.191$).
CONCLUSION: It is thus evident from the results that continuous inhalation of concentrated oxygen in pauses between repeated exertions on a ski simulator had no effect on increasing performance nor on any decrease in blood lactate concentrations after undergoing the tests, compared to placebo.

IMMEDIATE EFFECT OF CORE TRAINING ON THE SHOULDER MUSCULAR STRENGTH AND PULL MOTION IN SWIMMING

JIGAMI, H.

KOKUSHIKAN UNIVERSITY

INTRODUCTION:In competitive swimming, on-the-ground training called dry-land training is conducted to improve swimming performance and prevent injury before and after underwater training. This training program includes stretching, core muscle training, and strength and endurance muscle training. Therefore, the purpose of each training component is ambiguous. The purpose of this study was to clarify the immediate effect of core muscle training, which is commonly performed by many people, on shoulder muscle strength and on the pull motion in the water.
METHODS: Twelve swimmers enrolled in Japan intercollegiate championship division I participated in this study. The subjects performed eight types of core training mainly focusing on draw-in and stabilization training. The swimming time for 15-m swimming with pull motion without kick was measured after measuring shoulder muscular strength on both sides before and after core training. Shoulder muscle strength was measured using a handheld dynamometer (Mobie; Sakai Medical Co., Ltd.) in three different positions, namely entry-catch phase (catch phase), pull-push phase (pull phase), and finish phase. For the statistical analysis, a paired t test was conducted, and the significance level was set to 5%.
RESULTS: The right and left shoulder muscle strength before/after core training were 13.7/15.7 and 13.0/14.4 kgf in the catch phase, 13.8/15.3 and 14.9/16.3 kgf in the pull phase, and 9.4/10.8 and 11.3/12.1 kgf in the finish phase, respectively. Significant improvements were observed in the muscle strength on both sides in the catch phase after core training, although improvements were observed in all the phases. In addition, 15-m swimming speed significantly increased from 1.33 m/s to 1.37 m/s after core training ($p < 0.05$).
CONCLUSION: Previous studies showed that the core is the foundation for the movements of the upper and lower limbs. The results of this study clarified that shoulder muscle strength was improved instantaneously when core training was performed. In addition, the muscle strength in the catch phase greatly contributed to the improvement of the pull-motion swimming speed in all the phases. This improvement may be attributed to the effect of core training not only on shoulder muscle strength but also on underwater posture. Core training is clearly effective for immediate performance improvement in swimming.

DO STRIKER OUTPERFORM DEFENDER IN GENERAL-PERCEPTUAL COGNITIVE ABILITIES?

SCHUMACHER, N., BRAUMANN, K.M., REER, R.

UNIVERSITÄT HAMBURG

INTRODUCTION:Various studies examined the importance of sports-specific cognitive and perceptual skills in soccer (Ward & Williams, 2003). However, the relevance of general perceptual-cognitive abilities and the role of position is not clarified in detail (Schumacher et al., 2018). The purpose of this study was to investigate the differences between position groups with regard to sustained attention, selective attention and reaction abilities in highly talented soccer players.
METHODS: 147 highly talented male soccer players (14.8 + 2.6 yrs, age range 11 to 23 years) were included. The subjects played at the highest and 2nd highest national soccer competition level for their age and were recruited from a german youth academy of a professional soccer club. Computer-based selective attention, sustained attention, peripheral perception and reaction tests (using Vienna Test System) were performed. In the peripheral perception test stimuli were presented on the left and right side. The soccer players were subdivided into an offensive player group (OPG: striker, midfielder) and a defensive player group (DPG: goalkeeper, defender). Group differences were analyzed using independent t-tests.
RESULTS: Significant differences for position groups were observed, with regard to correct answers (OPG: 216.1 + 32.0; DPG: 231.3 + 26.0) in selective attention test ($t(140) = 3.05$, $p < 0.01$) and peripheral reaction time left (OPG: 0.71 + 0.09 sec; DPG: .67 + 0.10 sec) in peripheral perception test ($t(141) = 2.32$, $p < 0.01$). No differences were found for variables in the reaction and sustained attention test.
CONCLUSION: Our results indicate that defender and goalkeeper outperform striker and midfielder in general selective attention tasks and in left sided peripheral reaction tasks. Contrary to analyses with older participants no differences were found for sustained attention ailities. Additional research is needed to further clarify position-specific differences between left and right peripheral reaction time of highly talented soccer players.

CORRELATION OF STAR EXCURSION BALANCE TEST AND GOLF SWING EFFICIENCY.

PENG, Y.C.1,2, TANG, W.T.2

1:NATIONAL CHENG KUNG UNIVERSITY, TAIWAN 2:NATIONAL TAIWAN SPORT UNIVERSITY, TAIWAN

INTRODUCTION:The recent study reported the relationship between golf technique and dynamic balance (1). However, the results were examined by means of force plate such that the practical applications are limited. For example, the evidence may not allow to clarify the dynamic balance mechanisms underlying ball-striking efficiency. Accordingly, this study, using the Star Excursion Balance Test (SEBT), evaluated the dynamic balance ability. In addition, we categorized participants in to two groups based on the scores measured by SEBT (i.e., HDBA and LDBA, short for the high dynamic balance ability and low dynamic balance ability) to evaluate whether the dynamic balance is related to ball-striking efficiency.
METHODS: Sixty golfers (college athletes, 38 male and 22 female, aged 21.71±2.08 years, handicap < 5) without history of musculoskeletal disease participated in this study. All of the subjects were reported being right-handed. Each golfer performed the SEBT tests and performed the 7-iron tests to evaluate the ball-striking efficiency. Subjects were divided into two groups (HDBA and LDBA) on the basis of SEBT scores, resulting in 10 participants for each group. A Doppler radar launch monitor and associated software (TrackMan, Vedbaek, Denmark) was used to capture information on ball-striking efficiency during the golf swing.
RESULTS: The main results showed that the dynamic balance ability in the HDBA group (target foot mean: 100.62 ± 2.48%, Rear foot mean: 98.74±2.14%) were superior to those of LDBA group (target foot mean: 82.13±1.45%, Rear foot mean: 80.60±3.39%) ($p < 0.01$). No significant correlations were found for ball-striking efficiency across all participants.
CONCLUSION: Despite that the findings in Choi et al. (2016) highlights the relationship between golf techniques and dynamic balance, golf swing performance consists of multiple components that determine bodys competences, including coordination, strength, flexibility and balance, which has not been systematically examined. The present findings showed that the Star Excursion Balance Test is not an effective approach to evaluate ball-striking efficiency during the golf swing. Thus, we suggested that the Star Excursion Balance Test may be more appropriate for predicting injury risk, swing consistency and player physical monitoring.

PHYSICAL PERFORMANCE CHANGES AFTER 9 WEEKS OF CROSSFIT TRAINING IN COMPARISON TO THE OTHER FORMS OF HIT IN YOUNG MEN

WOLANSKI, P., MURAWSKA-CIALOWICZ, E.

UNIVERSITY SCHOOL OF PHYSICAL EDUCATION, WROCLAW

INTRODUCTION:Due to a variety of forms used in the training program, Crossfit is described as very intensive functional training – HIFT. It helps develop, among other things, endurance, strength, speed, power, flexibility, agility, motor coordination and pain tolerance. It happens because training units can be modified depending on training targets in which workout time and rest periods, intensity of exercise, number of series and repetitions, as well as the choice of external weight can be different. Crossfit includes elements of various types of intensive training programs, e.g.: IE, IT, SIT, HIPT, HIIT, HIET, HIT. Different training stimuli cause various structural and functional adaptive changes to occur in the body, and their direction depends on the duration time, intensity and type of the applied stimulus. Adaptive changes maintain a person's health potential and affect an improvement in sports result. The duration time of an exercise, its intensity and kinematics are the main variables determining adaptive changes of systematic training aimed at health improvement.
METHODS: The healthy young men trained 9 weeks. They were divided randomly into 4 training groups (Crossfit, HIPT, HIIT, HIET). Before and after the training program anthropometric measurements of body mass, BMI, and body composition were conducted as well as tests to assess their aerobic and anaerobic capacity. A progressive test was carried out on a treadmill and two Wingate tests on cycloergometers for lower and upper limbs.
RESULTS: VO2max (ml/kg/min) increased in the HIFT group +4,09±2,97 ($p<0,005$), in the HIPT group +2,92±2,03 ($p<0,05$), in the HIIT group +5,08±2,61 ($p<0,0005$), in the HIET group +2,66±1,53 ($p=0,056$). Relative maximum strength of lower limbs increased in the HIFT group +5,03±3,07% ($p=0,19$), in the HIPT group +6,14±6,44% ($p<0,05$), in the HIIT group +9,73±7,72% ($p<0,005$), in the HIET group +3,29±3,95%. In each group there was a decrease in body fat percentage: HIFT –2,60±1,39% ($p<0,005$), HIPT –1,53±1,31% ($p=0,07$), HIIT –3,04±1,72% ($p<0,0005$), HIET –1,61±1,46% ($p=0,074$).
CONCLUSION: There was an increase in VO2max, LBM, muscular strength and endurance in all the studied groups. There was a reduction in body fat (kg and %). The biggest changes were observed in the HIFT and HIIT groups. The obtained results are similar to the results reported by other authors (Eather et al., 2016; Goins, 2014; Murawska – Ciałowicz et al., 2015; Smith et al., 2013). Regardless of the applied high-intensity training form, after 9 weeks of training there is an improvement in aerobic and anaerobic capacity and a decrease in body fat (%).
Short, very intensive training can be used as a more attractive, especially for young people, form of exercise which results in an improvement in physical performance in a short space of time shaping their health potential at the same time.

ACUTE EFFECTS OF FATIGUE ON MARKERS OF SERVICE PERFORMANCE IN YOUNG TENNIS PLAYERS

AGUILERA-CASTELLS, J.1, BUSCÀ, B.1, PEÑA, J.2, MORELLÓ, I.3, VILA, P.1, PEDRAJA, G.1, RIERA, V.1, ARBOIX-ALIÓ, J.1

1: FPCEE BLANQUERNA RAMON LLULL UNIVERSITY , 2: UNIVERSITY OF VIC , 3: M&P TENNIS

INTRODUCTION:The acute effects of fatigue on serve speed, accuracy, and consistency were examined over consecutive days of prolonged tennis match play (2,3) or when a fatiguing exercise protocol was performed (1,4) in college or high-standard tennis players. However, these previous studies showed a lack of consensus in their results. For this reason, the aim of the study was to examine the effects of fatigue in the markers of serve performance in young tennis players after performing a fatiguing intermittent exercise protocol (FITEP).
METHODS: Ten young tennis players (age = 14.80±1.24 y, height = 1.63±0.05 m, weight = 54.24±9.24 kg) performed a speed velocity test before and after a FITEP (1 set of 12 repetitions of one serve followed by 5 forehand and 5 backhand drives. Each repetition lasted about 20 s with 20 s to recover) in a randomized order. The participants performed 24 first services and were previously instructed to "serve first serves as strong as possible and put the ball inside the score zones". The score zones were the T and the corner of the service square. The serve speed was measured using a radar gun (Pocket Radar Inc., Santa Rosa, CAN). The accuracy and consistency were calculated with an index. The accuracy index was the sum of the coefficient (0 = ball landing outside; 1= ball landing inside the serve square; 2 = ball landing inside the score zone) / total number of strokes. The consistency index was the number of balls landing within the score zones / total number of strokes. Lastly, paired samples T- tests were used to determine the FITEP effects on serve speed, accuracy, and consistency. All dependent variables data were expressed as mean ± SD.
RESULTS: For the analysed markers of serve performance, the serve speed, accuracy, and consistency showed a decrease in their performance after FITEP in respect to the performance achieved before the test. However, the comparison of the markers of serve performance before and after the test revealed no significant differences ($p>0.05$). Although the values of accuracy and consistency improved after the FITEP, these were not significantly ($p>0.05$) greater in comparison with the values before the test.
CONCLUSION: According to Rota et al. (4), FITEP elicits a significant decrease in serve speed, accuracy, and consistency. Overall, our results showed a tendency towards decreasing the markers of serve performance. However, the accuracy values were greater after the FITEP, as Maquirriain et al. (3) reported. These findings suggest that a FITEP may reduce the serve speed, accuracy, and consistency in young tennis players, but this kind of protocol must be designed following the demands of the sport and individualized with the level of the participants.

EFFECT OF STRENGTH TRAINING ACCORDING TO (TORQUE) DEVELOP MECHANICAL EXPLOSIVE POWER AND A SEVERAL KINEMATIC VARIABLES ON SOCCER PLAYER

JALAL, N., QADIR, N., DARWESH, N.

UNIVERSITY OF SULAIMANI

INTRODUCTION:According to torque theory, exercises is used for the purpose of increasing the speed of muscle work response to the elongation of the muscles working during preparatory section (force × length of the muscle in this situation) and contraction (to achieve muscular torque as a function of force × distance from the axis) according to the type of resistance used and upgrading of this resistance gradually, it is believed that it leads to improve elastic energy in accordance with the nature of the muscle fibers and the accompanying physiological nervous tension of muscle.
METHODS: Nineteen (19) youth football players aged between 19-17 years (mean ± SD: age 17.57 ± 0.534 years) were recruited from Nawroz Sport Club to take part in the study. The researcher used training programme which was based on specific strength exercises according to torque theory. The programme designed for eight (8) weeks (included 24 training units with 3 training units a week) with 20 specific strength exercises. The data were collected by using Dart fish and Kinovea analysis software, and the extraction of mechanical explosive and bio-mechanical variables of the two stages of the movement of collisions and beatings (the angle of the hip of a man kicking, the angle of the knee of a man kicking, the corner of the trunk, the corner of the hip of a man, the corner of the knee of a man, the horizontal distance between the ball and feet, height of the center of the weight of the body, body tilt angle)
RESULTS: The results from the training, explosive power of the two main value of (T) calculated was (2.368) and the value of the probability level was 0.028 which is a function at the rate of error (0.05) and the degree of freedom (20) This indicates that there were significant differences between the tests pre- and post- test, in the collision phase the angle of hip, the angle of knee, and the angle of the trunk. The angle of the knee distance between the ball and the foot center of the center of gravity and body angle of declined with values of 2.178 with hip, a distance between the ball and a fulcrum point were decreased as well, and all function at a level of significance (0.05) in front of the degree of freedom (20). This indicated that there were significant differences between the pre- and post-test; this means that the benefit of the post-test in mechanical variables was obtained. In terms of the beating phase the values were 2.384, 3.090, 3.640 and 2.475 for the variables (angle of the leg, the angle of the trunk, the angle of the head and the height of the center of the body weight) and degree of freedom was 20, this indicated that there was significant differences between the pre- and post -test and the benefit of the post-test in mechanical variables were obtained.
CONCLUSION: Strength workouts which were achieved in accordance with the force torque has positive impact to develop the value of variable (explosive mechanical ability), and strength ability according force torque theory have had a positive

THE RELATIONSHIP BETWEEN LIFTING SPEED OR POWER IN WEIGHT TRAINING AND THROWING PERFORMANCE IN ATHLETICS.

DAISUKE, Y.

TENRI UNIVERSITY

INTRODUCTION:The purpose of this study was to investigate the relationship between lifting parameters in the weight training and throwing performance for male collegiate students who specialize in throwing events in athletics.
METHODS: The subjects were two shot putters (Season Record; 13.12±1.56m, BH; 1.73±0.00m, BW; 89.5±19.1 kg), four hummer throwers (Season Record; 53.92±1.54 m, BH; 1.77±0.06 m, BW; 99.0±19.8 kg), three discus throwers (Season Record; 39.43±1.13 m, BH; 1.79±8.5 m, BW; 104±7.8 kg) and four javelin throwers (Season Record; 59.68±1.90 m, BH; 1.73±0.04 m, BW; 71.0±4.2 kg).
In this study, bench press, squat, power clean and snatch were selected as the training for measurement. We instructed to lift different weights (1RM, 90%1RM, 80%1RM, 70%1RM, and 60% 1RM) with maximum effort. As lifting parameters, the peak power and speed, average power and speed, and the average body weight power ratio during lift were measured at each weight using GymAwere.
In order to compare lifting parameters with throwing performance, the throwing record of each subject was converted to IAAF Score as throwing performance using the IAAF Scoring Tables of Athletics. The average value of IAAF score in each subject was 775.7 ± 78.4 points.
The Pearson product moment correlation coefficient was used to comprehend these relationships. In a case where significance level is below 5%, 2 variables were judged significant correlation.
RESULTS: In the results, no significant correlation was found between any lifting parameters of bench press and throwing performance. Meanwhile, peak speed at 70%1RM of squat was recognized to have a significant positive correlation (r=0.611) with throwing performance. In addition, average power, average speed, and the average body weight power ratio at 60%1RM of power clean (r = 0.571, r= 0.584, r = 0.665, respectively) and 90%1RM of snatch (r = 0.690, r= 0.653, r = 0.639, respectively) had a significant positive correlation with throwing performance.
CONCLUSION: These results suggest that squat, power clean, and snatch using lower limbs or a whole body are important physical factor than bench press using only the upper part of the body, and it is necessary to acquire dynamic exercise ability for all throwing events. In addition, it is suggested that demonstrating higher power and speed at 60%1RM of power clean and at 90%1RM of snatch might be key point in weight training. An interesting point in this study is that the weight of 60%1RM of clean and 90%1RM of snatch were about 80% of the body weight. In this research, it was not possible to target athletes with wide range of competition levels. In the future, it is important to investigate a lot of throwers to provide useful information for improving performance.

EFFECTS OF A COMPETITIVE PHASE FOLLOWED BY BLOCK PERIODIZED PREPARATION PHASE ON STRENGTH, POWER AND EXPLOSIVENESS IN A FEMALE WEIGHTLIFTER - A CASE STUDY

PÁLINKÁS, G., TRÓZNAI, ZS., UTCZÁS, K., PETRIDIS, L., SZABÓ, T.

UNIVERSITY OF PHYSICAL EDUCATION

INTRODUCTION:The purpose of this study was to examine the effects of a competitive period followed by a 6-week preparatory period on the maximal strength, power and sport specific performance in an international level female weightlifter. A 5-month period was divided into two parts: the first period was a competition phase, in which our athlete participated in five national and international competitions. The main goals of this period were to integrate the strength gained during the basic preparation period into technique in weightlifting exercises and to make these movements more efficient. Since previous measurements had shown weakness in hamstrings, it was also our goal to strengthen hamstring muscles. Competitive period was followed by a 6-week preparatory phase with block periodization.

Between the two phases 10 days rest period was given. Block periodized phase focused on the development of explosive power and on the maintenance of maximal force. During this period we used only submaximal loads. In this mesocycle the subject had 9 trainings per week: 2 technical, 2 strength (<90% of 1RM, moderate volume), 3 explosive power, 1 core strengthening and 1 training with classic weightlifting exercises.
METHODS: The subject of the study was a female weightlifter (age: 34.8 years; body height: 165 cm, body weight: 80 kg), member of the Hungarian national team. Measurements were performed three times; in the beginning and in the end of the competitive period and in the end of the preparatory period and included: power (power snatch, power clean), maximal strength (1RM back squat), and classic Olympic weightlifting (snatch, clean, clean and jerk) exercises. Laboratory testing included squat jump (SJ) on a force platform (HUR Labs).
RESULTS: The results showed no changes in the weightlifting exercises and in maximal strength after the competitive period, but there was improvement after the end of the 6-week period: 3.5% for power snatch (from 85 to 88 kg), 4.7% for power clean (from 105 to 110 kg), 9.6% for snatch (from 93 to 99 kg), 5.2% for clean (from 114 to 120 kg), 2.6% for clean and jerk (from 114 to 117 kg) and 6.3% for back squat (from 160 to 170 kg). SJ height increased gradually, with a total improvement of 15.8%.
CONCLUSION: The primary goal of this period was to integrate strength into the weightlifting movements, by improving also efficiency. Performance maintenance during continuous competitions may be quite challenging for coaches and athletes, since time for training interventions in this period is limited. By developing mainly explosiveness in the preparatory period, but without working on maximal strength, sport-specific performance in classic weightlifting increased. It was interesting that maximal strength increased by applying only submaximal loads and moderate volume. One possible explanation for the change in 1RM back squat (without maximal strength training) may be the strengthening of the core muscles.

THE RELATIONSHIP OF CARDIORESPIRATORY VARIABLES WITH BIOLOGICAL AGE IN 15-16 YEARS OLD MALE SOCCER PLAYERS

TÁNCZOS, B., GYÖRE, I., PETRIDIS, L., UTCZÁS, K., TRÓZNAI, ZS., SZABÓ, T.

UNIVERSITY OF PHYSICAL EDUCATION

INTRODUCTION:The purpose of this study was to evaluate the cardiorespiratory variables in relation to the biological maturation. Physical performance in young ages is correlated to biological maturation. Typically, more matured children achieve better results in physical tests than their less developed counterparts. However, it is still not clear, whether better endurance performance is attributed mostly to training adaptation or solely is the result of the different morphology of the more matured athletes.
METHODS: 88 male soccer players participated in the study (age: 15.9±0.5 years; height: 176.1 ± 5.6 cm; body weight: 65.4±7.2 kg). Cardiorespiratory variables were measured on a treadmill using a vita maxima protocol. Gas analysis was measured with a Vmax device.
The body composition of athletes was estimated by Drinkwater-Ross four-component model. Biological maturation was estimated based on morphological age, which includes growth charts of different body size measures of Hungarian children (Meszaros-Mohacsi method, 1983). The players were then divided into three groups based on the difference between morphological and chronological age in half year intervals (less developed <-0.5 years, normal: ±0.5 years, more mature: >+0.5 years). ANOVA was used to compare the results of the groups and Pearsons correlation was performed to establish the relationship between anthropometric and spiroergometric variables.
RESULTS: The average chronological age of the 3 groups was 15.9 years. The morphological average age of the less developed group was 15.1 years, of the normal group was 15.8 years and of the developed group 16.7 years. There were no differences between the groups in the chronological age and in body height, while in body mass and in the plastic index (the sum of shoulder width, forearm and arm circumference) all 3 groups differed significantly. Muscle mass was different between the 3 groups, but there was no difference in fat percentage. The less developed group had significantly lower values compared to the normal and to the more matured group in ventilation (110.8 l/min vs. 119.0 l/min and 120.5 l/min respectively), in max. oxygen uptake (3529 ml/min vs. 3798 ml/min and 3972 ml/min respectively) and in oxygen pulse (18.1 ml vs. 19.6 ml and 20.8 ml respectively), but there was no difference between the groups in the relative values. Absolute power values differed significantly between all three groups. There was a moderate to large correlation between chest circumference and max. oxygen uptake ($r = 0.61$; $p < 0.001$).
CONCLUSION: The lack of differences in relative values suggests that the differences observed in absolute values are not the result of training adaptation, but rather of the morphological differences, including body weight and the plastic index. The latter represents mostly the musculoskeletal robustness of an athlete, which was also reflected in the power values, since higher power of advanced athletes was associated with increased muscle mass.

CHANGES IN HIGH INTENSITY ACCELERATIONS AND DECELERATIONS BETWEEN SPECIFIC POSITIONS ACCORDING TO THE GAME QUARTERS OF U18 ELITE BASKETBALL PLAYERS

FERNÁNDEZ-VALDÉS, B.1, VÁZQUEZ-GUERRERO, J.2, JONES, B.3,4,5,6, MORAS, G.1, RECHE, X.2, GUDELIS, M.2, SAMPAIO, J.7

1: INEFC-UB; 2: FC BARCELONA; 3: LEEDS BECKETT UNIVERSITY; 4:LEEDS RHINOS; 5:YORKSHIRE CARNEGIE; 6:THE RUGBY FOOTBALL LEAGUE; 7:RESEARCH CENTER IN SPORTS SCIENCES, HEALTH SCIENCES & HUMAN DEVELOPMENT

INTRODUCTION:Acceleration is vital in decisive activities in order to obtain advantages during team sports. Therefore, in order to quantify external load in team sports it is important to also describe the number of high intensity actions such as accelerations and decelerations [1]. Thus, the aim of this study was to compare high intensity accelerations (> 2 m·s-2) and decelerations (< -2 m·s-2) between specific positions (Centers (CT), Forward (FW) and Guard (GD)) during U18 elite basketball games according to the game quarter.
METHODS: Data were collected from ninety-four male subjects (age: 17.4±0.7 years; height: 199.0±0.1 cm; body mass: 87.1±13.1 kg), competing in the Euroleague Basketball Tournament. Players activity was measured using a portable LPS (WIMU PRO). The following variables were measured and reported: high intensity accelerations (> 2 m·s-2) and decelerations (< -2 m·s-2). A linear mixed-effects model was used to model the main and interactive effects using PASW Statistics 21 (Chicago, IL, USA). "quarter" (i.e.,Q1, Q2, Q3 or Q4) and "position" (i.e., Center, Forward or Guard) were treated as the fixed effects, whereas the random effects were "ID Player" and "match-code". Then Magnitude-based inferences were applied using the estimates from the linear mixed model (representing percentage differences between sections by positions) and were compared against a smallest worthwhile effect threshold equivalent to 0.2 of the between-subject standard deviations using a spreadsheet [2]. Effects were classified as unclear if the percentage likelihood that the true effect was positive and negative were both >5%. Otherwise, the effect was deemed clear, and was qualified with a probabilistic term for

increase or decrease using the following scale: <0.5%, most unlikely; 0.5-4.9%, very unlikely; 5-24.9%, unlikely; 25-74.9%, possible; 75-94.9%, likely; 95-99.5%, very likely; >99.5%, almost certainly [2]. Also, the comparisons were assessed via standardized mean differences (Cohen´s d) and respective 90% confidence intervals. Thresholds for effect sizes statistics were <0.20, trivial; 0,20-0,59, small; 0.6-1.19, moderate; 1.20-1.99, large; and >2.0, very large [3].
RESULTS: When high intensity accelerations and decelerations were compared between the baseline (Q1) and the subsequent quarters (Q2, Q3 and Q4), there were moderate changes and very likely-almost certain decreases in the last quarter for all positions.
CONCLUSION: Based on these findings a significant reduction in high intensity accelerations and decelerations occurs during basketball, especially between first and last quarter in all playing positions.

THE EFFECT OF GROUP EXERCISE FREQUENCY ON HEALTH-RELATED PHYSICAL FITNESS IN JAPANESE ELDERLY

ISHIZAKI, S., ISHIHARA, Y., ISHIZAKI, J., KIMURA, T., MACHIDA, S., NAITO, H.

SHIBAURA INSTITUTE OF TECHNOLOGY

INTRODUCTION:We have shown that regular exercise for regional elderly people is effective for improving health-related physical fitness (2016). However, it is not clear how the difference in exercise frequency affects health and fitness. Therefore, the purpose of this study was to investigate the effect of exercise frequency on health-related physical fitness in Japanese elderly.
METHODS: Forty healthy people (age; 69.0±4.5years) volunteered to participate in this study. Subjects were divided into exercise groups once a week (G1) and groups once every two weeks (G2). Subjects participated in 6-month group exercise class (90min.). This exercise program consisted of 15 min. of warm-up and stretching, 20 min. of resistance exercise, 10 min. of step exercise, 20 min. of endurance-type exercise (walking), 20 min. of ball exercise (recreation), and 5 min. of cooling down. All exercise session was led by trained fitness instructors and supervised by the researchers. After the every exercise session, subjects were recorded Borg scale. Before (pre-) and after (post-) the group exercise classes, the following physical performances were measured; hand grip strength (HG), chair stand (CS), arm curl (AC), sit-up (SU), timed up & go (TUG), sit & reach (SR), back scratch (BS), functional reach (FR), 10-m walking (10-mWK), 10-m obstacle walking (10-mOWK) and 6-min walking (6-MW). In addition, blood pressure, brachial-ankle pulse wave velocity (baPWV), body composition, blood property, and 36-Item Short Form Survey (SF-36) were measured before and after the course.
RESULTS: Participation rate of the two groups exercise class was 90.1±5.2% (G1) and 95.1±8.8% (G2). Borg scale in the exercise class was 12.8±.0.7% (G1) and 12.4±.0.7% (G2). There were not significantly changed in body weight, %fat, fat, lean body mass, and waist circumference from pre to post exercise class. Additionally, in both group, systolic blood pressure and baPWV was not significantly decreased after the exercise. On the other hand, HG, CS, AC, SU, SR, BS, and 6-MW were significantly increased after 6 months in both groups. Time of TUG, 10-mWK, and 10-mOWK were significantly decreased after 6 months in both groups. Furthermore, this increase was significantly greater in G1 compared to G2.
CONCLUSION: In conclusion, the difference of the effect by the exercise frequency was not shown in this study. For a cause, daily active mass may influence it. It will be necessary to examine it in consideration of daily active mass in future.

DOES MUSCLE STRENGTH AND STRENGTH BALANCE OF KNEE EXTENSORS AND FLEXORS DIFFER BY PLAYING POSITION OF SOCCER PLAYERS?

MISJUK, M., RANNAMA, I., ZUSA, A.

TALLINN UNIVERSITY

INTRODUCTION:Playing soccer in different positions demands different physical abilities, different morphotypes and specific strength (1, 5). Soccer players have very often muscular strength asymmetries (2, 4). Functional asymmetry may cause performance reduction and may increase the risk of injury (3). Playing position is one out of five factors that affect functional asymmetry (3).
The purpose of this study is to compare knee extensors and flexors absolute and relative peak torque; and bilateral strength balance and H/Q ratio of soccer players according to playing positions.
METHODS: The participants of this study are 102 male soccer players (22.9±4.4yrs, 181.1±6.7cm, 76.6±8.2kg) of professional Estonian Premium League teams: 41 defenders, 40 midfielders and 21 forwards. Athletes completed three different types of tests on isokinetic dynomometer. During the testing they made five concentric repetitions at 300°/s, three concentric repetitions at 60°/s and three eccentric repetitions at 60°/s. The best result of all repetitions is used in the statistical analysis. The one-way ANOVA and Bonferroni methods are used to compare the strength parameters between positions. The Student t-test is used to compare dominant and non-dominant leg.
RESULTS: The absolute peak torque values of midfielders are statistically significantly smaller than defenders and forwards at angular velocity 60°/s on concentric and eccentric mode. No statistically significant differences are found between soccer players positions at angular speed 300°/s. The relative peak torque does not differ statistically significantly between players position. Defenders have statistically significantly stronger dominant leg compared to non-dominant leg in the concentric and eccentric mode at angular velocity 60°/s. No statistically significant differences are found between playing positions in bilateral strength balance and H/Q ratio. Players in different playing position have different knee extensors and flexors strength values, but no differences are observed between playing position and knee extensors and flexors strength balance.
CONCLUSION: In sum, we can say that midfielders have lower absolute strength level that at least partly is related to their lower body mass. We find no position specific differences in muscle balance parameters, while defenders have stronger dominant side and have direction-specific differences in knee flexors strength at lower testing speeds in concentric and eccentric mode. We find also that forwards demonstrated higher unilateral strength balance of the dominant leg in low concentric speed.

DETERMINATION OF THE ANAEROBIC THRESHOLD FROM STRIDE CONTACT TIME IN RUNNING

SENTIJA, D., MARSIC, T.

FACULTY OF KINESIOLOGY, UNIVERSITY OF ZAGREB

INTRODUCTION:During graded treadmill running neuromuscular and metabolic changes, which determine the anaerobic threshold, are associated with changes of specific kinematic parameters. The main objectives of this research were to investigate: 1) the relationship between stride contact time (CT) and running speed during incremental running to exhaution, and the possible presence of a threshold

(nonlinear change in the trend) for contact time (CTh); 2) the relationship between the ventilatory anaerobic threshold (ATh, respiratory compensation point) and the CTh.
METHODS: Twenty-three PE students were subjected to an all-out incremental treadmill test, with measurement of gas exchange (VO2, VCO2) and kinematic parameters. Independent evaluators defined the ATh (modified V-slope method) and CTh thresholds. The APAS system (Ariel Dynamics, USA) with surface markers was used to measure the stride contact time, and the Quark b2 (Cosmed, IT) system for spiroergometry data. Student's t-test, correlation coefficient (r), and limits of agreement (LoA) were used to compare the ATh and CTh thresholds obtained in the graded exercise test.
RESULTS: In 19 subjects CTh was determined as a change in the trend of CT, i.e. the point of stagnation or slower decrease of stride contact time with increasing running speed. In the remaining 4 subjects contact time decreased faster at speeds above CTh. A strong relationship between ATh and CTh ($r = 0.86$, $p < 0.01$) was determined. The average values of ATh and CTh did not differ significantly (13.0+/-1.7 and 13.2+/-1.7 km/h, respectively), although a trend towards somewhat higher values for CTh was present (LoA = 0.2 ± 2.1 km/h).
CONCLUSION: We conclude that, during a graded treadmill test, there is close coupling between changes in the trend of stride contact time and changes in gas exchange parameters that determine the anaerobic (second ventilatory) threshold. The results of the study give the opportunity for developement of a new method for anaerobic threshold determination by stride contact time measurement during graded treadmill running.

EFFECT OF HEAVY STRENGTH AND POWER TRAINING ON THE ORTHOSTATIC TEST

SCHÄFER OLSTAD, D.1, MIDTTUN, M.2, HELLAND, C.2, SAELAND, F.2, PAULSEN, G.2
1> POLAR ELECTRO OY, 2> NORWEGIAN OLYMPIC AND PARALYMPIC COMMITTEE AND CONFEDERATION OF SPORTS

INTRODUCTION:Measures of heart rate (HR) and heart rate variability (HRV) are established methods to assess recovery status of athletes. As most studies investigated the effect of aerobic endurance training on the orthostatic test, it remains unknown whether orthostatic test is suitable to assess recovery status after heavy strength and power training. The aim of this study was therefore to assess the effect of heavy strength and power training on HR and HRV in the orthostatic test.
METHODS: Nine healthy young male and female recreational athletes with more than 3 years' experience in strength training participated in this study. After a familiarization session, one power and one heavy strength training were performed in randomized order. Heavy strength training included 5x5 RM squat, front squat, trapbar deadlift, bench press, narrow grip bench press, and push-ups with external loading. Power session included 5x5 (50% of the heavy strength training session loads) jump squats, push press, trapbar jumps, bench press throws (wide and narrow grips) and push-ups (only body weight). Resting periods were 2 min. Orthostatic test (10min supine followed by 5min standing) was performed pre, 10 min post, 24 h and 48 h after the sessions. Data was recorded with Polar H10 and analyzed with Kubios HRV. HR and the square root of the mean squared difference of successive RRI (RMSSD) were calculated for 2 min segments before and 1 min after standing up.
RESULTS: Wilcoxon tests showed that HR supine and standing was significantly (both $p=0.043$) higher 10 min post compared to before the heavy strength training session (mean±SD; 73±12 bpm vs 64±12 bmp for supine and 95±10 bpm vs 84±13 bpm for standing, respectively) while there was no significant change in RMSSD (mean±SD; 35±23 ms vs 67±56 ms for supine and 12±3 ms vs 20±8 bpm for standing, respectively). RMSSD in supine and standing was significantly (both $p=0.046$) lower 10 min after the power intervention compared to before (mean±SD; 48±5 ms vs 82±75 ms for supine and 15±6 ms vs 25±16 ms for standing, respectively), while there was no significant change in HR (mean±SD; 72±11 bpm vs 64±15 bpm for supine and 95±11 bpm vs 82±18 bpm for standing, respectively). There was no significant difference in the change between pre and post session HR and RMSSD comparing heavy strength and power training.
HR and RMSSD were unaffected by either heavy strength or power training after 24 and 48 h of recovery.
CONCLUSION: We conclude that the orthostatic test results were only altered immediately after, but not at 24 and 48 of recovery from strength and power training. We suggest that orthostatic test can be used to assess acute recovery shortly after exercise but might not be suitable to detect fatigue induced by heavy strength and power training on the following day(s).

MUSCLE ACTIVITY IS INCREASED BY LOOKING AT THE TARGET MUSCLES AND FOCUSING ON MUSCLE SQUEEZING.

FUJIWARA, S., NAKAZATO, K., OKADA, T.
NIPPON SPORT SCIENCE UNIVERSITY

INTRODUCTION:Two types of attentional focuses have been identified: internal and external. It is known that internal focus increases muscle activity by conscious of muscle(1). Thus, internal focus is said to be a mind muscle connection in the bodybuilding and it is useful if muscle development is the purpose. External focus(EF) enhances motor performance by conscious of object(2). However, there is no study on internal focus using visual sense. In the case of conventional internal focus(CIF), subjects were instructed to look forward and focus on internal focus. Therefore, the purpose of this research is to investigate whether internal focus using visual sense can enhance muscle activity.
METHODS: Nine resistance-untrained men were familiarized with the procedure and one-repetition maximum (1RM) test during session 1. In session 2, subjects performed one hand preacher curl machine three repetitions at 30% 1-repetition max (1RM) while surface electromyographic(sEMG) activity was recorded from the long head of biceps brachii muscle (BB). There was a two minute rest period in between the sets. The order of instructions was randomized between subjects. The subjects was instructed to look forward and focus on lifting the hand bar (EF). In the case of CIF, subjects were instructed to look ahead and focus on muscle squeezing.
Furthermore, subjects were instructed to look at muscles and focus on muscle squeezing(LIF). Mean normalized root mean square EMG activity was calculated during 3 repetition in each condition. Analyses were done with paired tests with Bonferroni's correction.
RESULTS: LIF(55.9±9.8%MVC) showed a significant increase in EMG activity than EF(29.8±3.98%MVC) ($p<0.05$).
The rate of change between LIF and EF was 88% ($p<0.05$). There was no statistically significant difference between the EF(29.8±3.98%MVC) and CIF(37.8±4.9%MVC)($p>0.05$).The rate of change between EF and CIF was 27%($p>0.05$).EMG activity was not different between LIF(55.9±9.8%MVC) and CIF(37.8±4.9%MVC)($p>0.05$).The rate of change between LIF and CIF was 48%.
CONCLUSION: In this study, it was found that internal focus is more effective by using visual. Especially for resistance training beginners, it is thought that consciousness becomes easy by looking at the target muscles. Therefore, it suggested to enhance muscle activity and promote muscle development.

EFFECTS OF STRETCHING ON MAXIMUM SQUAT STRENGTH AND LOWER LIMB LEAN MASS DURING A DETRAINING PERIOD IN YOUNG MALES

DORADO, C.

A RESEARCH INSTITUTE OF BIOMEDICAL AND HEALTH SCIENCES , LAS PALMAS DE GRAN CANARIA UNIVERSITY, CANARY ISLAND, SPAIN. B FACULTAD DE CIENCIAS DE LA ACTIVIDAD FÍSICA Y EL DEPORTE, UNIVERSITY OF L

INTRODUCTION:Alternating cycles of training and recovery is important to improve performance, and reduce the risk of maladaptation and injury. Stretching exercises are widely used in sports to enhance performance and also to reduce the risk of injury. Stretching before athletic events demanding muscle strength and power may impair performance. Little is known about the long-term effects of stretching on muscle strength and lean mass. The main aim was to determine the effects of stretching during 8 weeks of detraining, after 4 weeks of heavy resistance training (HRT), on maximal strength and lean mass.
METHODS: Forty-three healthy physically active males (age 18-32 years) without previous experience in HRT conducted 4-weeks of velocity-based HRT using full-squat exercise (3 s/w). The following 8 weeks all participants performed 1 HRT session every 15 days (detraining period). All HRT sessions were performed at 70% of 1RM (3 sets, 6 reps, 4 min rest) allowing a repetition velocity loss of 20% into each set. During the detraining period, the participants were randomly divided in 2 groups. In one group (FLEX; n=28), the lower extremities were passively stretched by a physiotherapist (3 s/w, 4 lower extremity exercises, 30 s stretch and 30 s rest, repeated twice), while the other group (CG) did not perform any stretching. Pre-training and post-training assessments, at the end of training and detraining periods, included dual X-ray absorptiometry and one-repetition maximum (1RM).
RESULTS: After the first 4-weeks of resistance training, FLEX and CG increased 1RM 18% and 22%, respectively (both $p<0.01$). The legs lean mass also increased in the FLEX and CG, 2.1% and 3.5%, respectively (both $p<0.01$). After the 8-weeks of detraining, 1RM remained in both groups (FLEX $p=0.68$, CG $p=0.14$), whereas the legs lean mass remained in FLEX ($p=0.24$) and decreased in CG (2.2%, $p<0.01$).
CONCLUSION: A main finding of the present study is that performing one heavy resistance training session every 15 days using the full-squat exercise, in combination with stretching exercises (3 d/w), allow to maintain maximum squat strength and legs lean mass in healthy physically active males. In turn, performing only one training session every 15 days without stretching also maintain maximum squat strength but have a detrimental effect on legs lean mass. These findings suggest that stretching may have a protective effect on the loss of lean mass as a consequence of detraining. These results could be of assistance when designing training programs aimed at maintaining maximal strength and muscle mass during competitive, recovery or detraining periods.

EFFECT OF A 6-WEEK KETTLEBELL TRAINING PROGRAM ON SWIMMING PERFORMANCE OF YOUTH SWIMMERS

STANULA, A.1, KARPINSKI, J.1, REJDYCH, W.1, SADOWSKI, W.1, SWINAREW, A.2, POPRZECKI, S.1, KRUZOLEK, P.4, KUNICKI, M.5

1:THE JERZY KUKUCZKA ACADEMY OF PHYSICAL EDUCATION, KATOWICE, POLAND, 2:UNIVERSITY OF SILESIA, KATOWICE, 3:SCHOOL COMPLEX OF SPORTS CHAMPIONSHIPS, RACIBÓRZ, 4:COLLEGE OF PROFESSIONAL STUDIES, RACIBÓRZ

INTRODUCTION:Swimming performance is influenced by a complex interaction of physiological, morphological, neuromuscular, biomechanical and technical factors [Crowley et al. 2017]. It is widely accepted that swimming performance is highly dependent on power and muscular strength [Sharp et al. 1981]. Therefore appropriate strength training of the whole body seems to be one of the key elements determining the effectiveness of the training process, as well as the progression of results achieved by swimmers. The purpose of this study was to examine the effect of a 6-week kettlebell training program aimed at strengthening the whole body to improve the effectiveness of selected elements of a swimming race in group of polish youth swimmers.
METHODS: Twelve youth male swimmers participated in the study (age 16.9±0.99 year; weight 72.9±4.88 kg; height 1.81±4.01 m; %FAT 11.13±2.04%). The swimmers were randomized to an kettlebell group (KB) of 6 swimmers and a control group (CG) also 6 swimmers. Both groups of swimmers carried out the same training program in the water (volume and intensity), while swimmers with KB additionally carried out specialized kettlebell training program (SKTP), which took place 3 times a week for 6 weeks. SKTP consist of six exercises with kettlebells: goblet squat, deadlift high pull, press, swing, jump, lunges. Before and after a 6-week kettlebell training program selected parameters of the start, turn and swimming under 50-m freestyle race conditions were analysed in both groups. To compare the effects of training on all measurements variables, a 2 (training group) × 2 (test time point) factor analysis of variance with repeated measures for the factor time point was used.
RESULTS: After the end of the 6-week training in KB was observed improve on measured parameters (pretest vs. posttest): 1) swim start: Reaction time [s] (0.79±0.03 vs. 0.73±0.02), Time in the air [s] (0.30±0.06 vs. 0.34±0.05; $p<0.05$), Dive angle [degrees] (36,17±4.07 vs. 28.5±7.77; $p<0.01$); Time 15 m [s] (6.87±0.28 vs. 6.76±0.29); 2) swimming technique: Stroke rate [cycles/s] 1.00±0.12 vs. 0.96±0.14; $p<0.05$), Stroke length [m] (1.89±0.25 vs. 2.00±0.22), Total time 50 m [s] 26.68±0.59 vs. 26.49±0.82); 3) turn: Time in 5 m turn segment [s] (5.68±0.19 vs. 5.03±0.24).
CONCLUSION: There are many papers on the impact of land training on performance in swimming sport, however, the results of these studies are not consistent. For example, Tanaka et al. (1993) suggest that the increase in strength through a resistance land training does not affect the swimmers driving force in the water, and therefore, does not improve swimming performance. Based on the conducted experiment, it can be concluded that the described training affects the efficiency of swimming on a short distance. It is especially worth noting that in these studies, the improvement in the efficiency of individual swimming elements has translated into the final sports result, which is the time to swim the distance of 50 m.

SPECIFIC ROLLER SKIS GAMES AND ACITIVITIES FOR YOUNG NORDIC SKIERS AGED BETWEEN 12 AND 14 YEARS

KORBELAR, T., SUCHY, J., PERIC, T.

FACULTY OD PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY

INTRODUCTION:Roller skis are becoming more and more important in nowadays training sessions of cross country skiers due to the similarities in both movements. Roller skis are used as a training tool also in midget and juvenile categories. The only limiting factor is now the lack of closed asphalt routes. The situation is recently getting better thanks to the trend of building these tracks in the surroundings of many villages. Occasionally we can see even an asphalt track campus. This all helps to the safety of young athletes and increases

the demand for roller skis. Unfortunately, coaches often use adult or junior training models for children in the age of 12-14 and the games so necessary for this age are missing.
METHODS: A first method used in this work was available analysis of czech and international documents about games and activities. Then a collection of games and activities was made, which was customised for roller skis trainings. Furthermore, there was a verification of collection of roller skis games and activities with the help of a board of experts composed of experienced and licensed nordic skiers trainers and then nordic skiers experts. An unstructured interview was made with them followed by a discussion about each game and activity.
RESULTS: In the first part there is a chapter about an equipment used collection created by us. The main part is made of a customised and verified collection of roller skis´games and activities for young nordic skiers aged between 12 and 14 years. Board of experts made a verification added their ideas and suggestions to specific games and activities in the form tips and suggestion. A new chapter dividing the collection was created as a result of a discussion with the board of experts was created at the end of a final part. It was divided according to three main viewpoints, which are safety, space and a number of competitors.
CONCLUSION: At the end we have created an unique and verified collection of games and activities with a focus on roller ski designed for young skiers. In the collection there is 50 games and activities in total. These 50 games and activitites have been distributed into five subgroups. The focus of the first one is for warm up (15). Second group is for development of balance (11), third one is for development of speed (16), fourth one is for development of endurance (2) and last one for a modification of sport games (6). We hope this collection is going to reach a full use in professional trainning and public.

ASSESSMENT OF MULTISTEP DROP JUMP TEST ON THE BALL AND RACKET GAME PLAYERS

YOSHIDA, T.1, KAWAHARA, F.1, ZUSHI, A.1, ZUSHI, K.1, HAYASHI, R.2, TANIGAWA, S.1

1:UNIIVERSITY OF TSUKUBA, 2: GIFU UNIVERSITY

INTRODUCTION:Drop jump (DJ) is not only used as a training method for improving explosive power in numerous types of sports but it is also a method of performance evaluation. From the previous study, it is argued that in order to use DJ as a method of performance evaluation, the optimum drop height varies depending on the characteristics of target players and sports events (1). we investigated the characteristics of drop jump performance when using a several drop heights, including the high drop height, and the characteristics of changes in the force demonstration of the lower limb three joints for jumper. As a result, athletes who showed high drop jumping performance at low dropping height but who declined at high dropping height, as well as athletes whose jumping height also increases with the increase in the joint work of the lower limb 3 joints with increased dropping height (2). Although this study is only for jumper, there is a possibility that by using multiple several drop heights, the SSC abilities of ball players can be examined in detail. The purpose of this study was to evaluate the multistep DJ test in ball and racket game athletes according to changes in test performance, ground reaction force, lower limb joint kinetics with changes in drop height.
METHODS: Ball and racket game athletes performed the DJ for three drop heights (0.3 m, 0.6 m and 0.9 m). Participants were orally instructed to shorten the contact time as much as possible and to jump as high as possible. Three-dimensional coordinates of the 12 retroreflective markers fixed on each subject's body were obtained using a Vicon T20 system (Vicon Motion Systems Ltd.) with 10 cameras operating at 250 Hz. Ground reaction force was measured by a force platform at a rate of 1000 Hz. DJ-index indicates that the mechanical power per body mass during take-off was calculated by dividing the jump height by the contact time. The rate of change of the DJ-index (a/b) was the slope/intercept of the regression line (Y = aX+ b) derived from 3 values of the DJ-index for each participant. Joint work of the lower leg (take-off leg side) were calculated by using inverse dynamics. Relative work was calculated as the ratio of work for each joint relative to the total sum of work for the three lower limb joints.
RESULTS: The DJ-index, jump height, and contact time of each drop height were different for the event. Also, Joint work and relative work of the lower leg were different for the event. The rate of change of the DJ-index (a/b) were significant difference were indicated between the events for a/b.
CONCLUSION: Conclusion
To evaluate the jump performance of ball and racket game player, it is important to use a various range of heights including a higher drop height (approximately 0.9 m), because the DJ test at just 1 drop height cannot effectively evaluate performance.

ANALYSIS OF AEROBIC AND ANAEROBIC POWER FROM DIFFERENT SOCCER PLAYERS CATEGORIES IN BRAZILIAN FEDERAL DISTRICT

GARCIA, D., RAMOS, I.A., GUEDES, G.L., SOUSA, D.P., LEITE, C.D., MELO, G.F.

CATHOLIC UNIVERSITY OF BRASILIA

INTRODUCTION:Soccer (SC) is characterized by intermittent actions, in which players must be able of performing repeated runs at high intensity (sprints), by different distances with constant changes in their direction, for short recovery time spans. The aim of this study was to analyze aerobic and anaerobic power of soccer players from different categories during the preseason (1).
METHODS: Fifty-four SC, professionals (PRO; n=35; 25.57 ± 5.11 years, 77.31 ± 9.19 kg, 179.84 ± 7.19 cm, 10.24 ± 4.33% body fat) and Under-20 (U-20; n=19; 8.52 ± 0.61 years, 70.86 ± 5.85 kg, 177.24 ± 4.50 cm, 8.82 ± 3.12% body fat) underwent to weight, height, body fat, aerobic power (VO2max) and anaerobic power (Running Anaerobic Sprint Test - RAST) tests. Were calculated from anaerobic power, the peak power absolute and relative (PPabsolute; PPrelative respectively) and fatigue index (%FI). Statistical significance for all comparisons: $p \leq 0.05$ at t test.
RESULTS: Regarding aerobic power (VO2MAX), there wasn't significant difference between groups (PRO: 53.88 ± 4.22 ml/kg.min-1; UNDER-20 53.90 ± 3.67 ml/kg.min-1; p=0.992). The anaerobic power also not showed difference at absolutePP, (p = 0.057). Nevertheless, when analyzed the total body mass, the Under-20 (14.80 ±1.89 W/Kg) showed higher value than PG (12.48 ±1.63 W/Kg). On the other hand, the FI (%), has shown higher results for the Under-20 (51.33 ± 6.70 %) and the PG's (45.32 ± 6.66% ;p = 0.003).
CONCLUSION: PRO and U-20 did not showed significant differences in most of the variables studied, which would present specific distinctions and characterizations for each group. PRO has a lower relative power when compared to U-20, despite reporting a greater tolerance to effort, as shown by a lower percentage in the fatigue index, possibly attributed to the longer training time compared to the U-20. These results may suggest that trainings with characteristics of intermittent actions it has to be structured individually, specially in relation

to recovery intervals, because professional players show less fatigue index probably due to a motor-functional experience, whereas the Under-20 players find themselves in a transition phase, with different performance steps, state and energy reserves.

THE EFFECT ON MUSCLE ACTIVATION IN TRUNK AND LOW-LIMBS DURING SQUAT EXERCISE ON VARIOUS SURFACE.

SUK-HO, LEE., TAE-DONG, KWON., GI-DUCK, PARK., SEONG-DEOK, YOON., THE-HOON, LEE., SA-YUP, KIM., JOON-HO, HYEONG., JONG-RYUN, ROH.

KYUNGPOOK NATIONAL UNIVERSITY, KEIMYUNG COLLEGE UNIVERSITY, KEIMYUNG UNIVERSITY, KOREA INSTITUTE OF INDUSTRIAL TECHNOLOGY.

INTRODUCTION:This study tried to identify which muscle shows more effective muscle activity through distinctive exercise of squat, by measuring and comparing muscle activities of trunk muscle and lower limb muscles during exercising.
METHODS: A total of fifteen male university students who had no pain nor surgical history of the knee or hip, were selected as subjects. They were asked to perform floor squat, jummper squat, and dynairball squat 3 sets of 10 times for 4 weeks. The sequence of actions was performed randomly to exclude the effect of orders and to increase the objectivity of data. The significance level was set to .05.
RESULTS: The results of this study showed that the average muscle activity of rectus abdominis, biceps femoris, made a statistically significant difference during jummper, dynairball squats ($p < .05$), whereas the average muscle activity of soleus muscle indicated a statistically significant difference during jummper, dynairball squats ($p < .001$).
CONCLUSION: Over all, this study contributes to the field of strength and conditioning of physical therapy by examining how different squat exercise affects different muscle development. This study also provides insights into exercise program developments on how effectively strengthen the low limb muscles.

EFFECT OF SESSION RATING OF PERCEIVED EXERTION ON ATHLETIC PERFORMANCE DURING TRAINING PERIOD

LIN, H.S., PAN, Y.K., WU, M.H., CHIU, C.H.

NATIONAL CHINESE CULTURE UNIVERSITY., NATIONAL TAIWAN UNIVERSITY OF SPORT., TUNGHAI UNIVERSITY., NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION:Inappropriate training load may cause overtraining ,injury or reduce performance. Session Rating of Perceived Exertion (sRPE) often be used to monitor training volume.The purpose of this study was to observe the correlation between sRPE and athletic performance during the non-season training period.
METHODS: We recruited National Taiwan University of Sports track and field sprinters (n=32, male=24 female=8). During the 11-week training period, Participants maintain their regular training and recorded sRPE number after each training. We also collected the number of injured athletes per week and the exercise performance (100-meter sprint, vertical jump) before and after training .
RESULTS: 100-meter sprint velocity showed a significant increase in the between before and after training ($p < 0.05$). No significant correction was found between sprint velocity and sRPE, however, there was a significant positivity correlation between Training Monotony(TM) and the number of injured ($r=0.61/p<0.05$).
CONCLUSION: Our results showed that sRPE be used to monitor training volume that will prevent injury ratio.It is therefore vital that coaches give consideration to these mediators of sRPE training load.

THE PHYSIOLOGICAL CHARACTERISTICS OF THE FIRST SAUDI FEMALE SPORT SCIENCE UNIVERSITY STUDENTS

ALAHMADI, M.

TAIBAH UNIVERSITY

INTRODUCTION:For the first time in Saudi Arabia (SA), girls at public schools will be taught physical education. Recently, the new Physical Education and Sport Science major for girls opened at a few Universities in SA. Therefore, the aim of this study was to assess the physiological characteristics of the first Saudi female Sport Science University students.
METHODS: 40 female university students (mean ± SD, age, 18.7 ± 0.60 years; body mass, 54.7 ± 10.8 kg; height, 157 ± 5.5 cm) participated in this study. The Queens College step test was performed to estimate maximal oxygen consumption (VO2max). Body fat percentage (BF%) was determined by using bioelectrical impedance scale. Hand grip strength was measured by hand grip dynamometer and flexibility was determined by using Sit-and-Reach Test.
RESULTS: The mean (±SD) of an indirectly predicted VO2max was 36.5 ± 3.6 (ml/kg/min). The mean (±SD) of BF%, hand grip strength, and flexibility were 32.3 ± 7.8 (%), 17.4 ± 5.0 (kg), and 16.6 ± 3.0 (cm), respectively.
CONCLUSION: It is concluded that VO2max , hand grip strength, and flexibility were lower and BF% was higher in Saudi female university students, compared to those reported in international literature.
